TACO Tier 3 Demonstration
Roxana, Illinois
1191150002 – Madison County
Equilon Enterprises, LLC d/b/a Shell Oil Products US

Dear Ms. Munie:

On behalf of Equilon Enterprises, LLC d/b/a Shell Oil Products US (SOPUS), AECOM is submitting the enclosed TACO Tier 3 Demonstration (Report). SOPUS' goal with this submittal is to present and obtain approval from the Illinois Environmental Protection Agency (IEPA) for site-specific Tier 3 remediation objectives (ROs) for soil gas. Based on a comparison of site data to the calculated Tier 3 soil gas ROs, it is SOPUS's opinion that the site data meets the proposed RO's. However, in order to determine this compliance, rebound monitoring must be completed with the Regenerative Thermal Oxidizer (RTO) turned off. Once the RTO Soil Vapor Extraction (SVE) system operations are turned off, a rebound monitoring program will be initiated to assess compliance with the soil gas ROs in the Village of Roxana and the Public Works Yard. This rebound monitoring program along with the ROs are proposed within this submittal.

The Report is presented in two parts for ease of review:

Part 1- Site Characterization Summary, presents an overview of site history and past investigations, site geology and hydrogeology, the nature and extent of petroleum hydrocarbons in soil, soil gas and indoor air, as well as temporal changes in soil gas since the startup of the SVE system. Part 1 also presents a conceptual site model (CSM) for both pre-SVE and conditions based on soil gas data through 4th quarter 2016 (4Q16) presented in the Site Characterization Summary. The presentation of temporal data provides strong evidence supporting the effectiveness of the SVE system in remediating soil gas which supports the development of Tier 3 ROs and for establishing a path forward to permanent SVE system shutdown and dismantlement.

Part 2- Tier 3 Proposal, begins with a summary of the key site characterization conclusions from Part 1, then presents an introduction to the Johnson & Ettinger (J&E) and Little, Daisy, Nazaroff (LDN) models and the overall mass flux model approach to calculating soil gas concentration end points that are protective of indoor air. Part 2 discusses the inputs used to calculate the LDN model values and presents the modeling results. Based on the results of the LDN modeling, Tier 3 ROs are presented. Using the proposed remediation objectives, Part 2 outlines suggested system shutdown and a rebound monitoring program.

AECOM

AECOM and SOPUS would like to schedule a meeting to discuss the contents of the TACO Tier 3 Demonstration. If you have any questions during your review, please contact Kevin Dyer, SOPUS Senior Principal Program Manager, at kevin.dyer@shell.com (618-288-7237), or Robert Mooshegian at robert.mooshegian@aecom.com (314-743-4106).

Sincerely,

AECOM, on behalf of Shell Oil Products US

Claire Mitchell, P.E.

TACO Tier 3 Demonstration – Corrections to Part 1, Table 3-4 and Appendix 3-E
Roxana, Illinois
1191150002 – Madison County
Equilon Enterprises, LLC d/b/a Shell Oil Products US

Dear Ms. Munie:

On behalf of Equilon Enterprises, LLC d/b/a Shell Oil Products US (SOPUS), AECOM is submitting a corrected version of Part 1 Table 3-4, Summary of Soil Gas Analytical Detections and Screening Results – VOCs, and Part 1 Appendix 3-E, Cumulative Summary of Soil Gas Analytical Detections and Screening Results – VOCs, as well as a corrected Part 1 Table of Contents. Data associated with certain vapor monitoring points were inadvertently not included in the aforementioned Table and Appendix in the TACO Tier 3 Demonstration transmitted to you on April 6, 2017. Paper copies of the corrected Table of Contents and Table 3-4, and a DVD containing the revised TACO Tier 3 Demonstration are included. Replacement pages are noted as "Revision 1".

If you have any questions, please contact Kevin Dyer, SOPUS Senior Principal Program Manager, at kevin.dyer@shell.com (618-288-7237), or Robert Mooshegian at robert.mooshegian@aecom.com (314-743-4106).

Sincerely,

AECOM, on behalf of Shell Oil Products US

Claire Mitchell, P.E.

ILLINOIS EPA RCRA CORRECTIVE ACTION CERTIFICATION

This certification must accompany any document submitted to Illinois EPA in accordance with the corrective action requirements set forth in a facility's RCRA permit. The original and two copies of all documents submitted must be provided.

1.0 Facility Identification

Name: WRB Refining LP Wood River Refinery
County: Madison
Street Address: 900 South Central Avenue
Site No. (IEPA): 1191150002
City: Roxana
Site No. (USEPA): ILD080012305

2.0 Owner Information

Name: Not Applicable
Mail Address:
City:
State: Zip Code:
Contact Name:
Contact Title:
Phone:

3.0 Operator Information

Name: Equilon Enterprises LLC dba SOPUS
Mail Address: 17 Junction Drive, PMB #399
City: Glen Carbon
State: IL Zip Code: 62034
Contact Name: Kevin Dyer
Contact Title: Senior Principal Program Manager
Phone: 618-288-7237

4.0 Type of Submission (check applicable item and provide requested information, as applicable)

☐ RFI Phase I Workplan/Report
☐ RFI Phase II Workplan/Report
☐ CMP Report;
☑ Other (describe): TACO Tier 3 Demonstration: Parts 1 and 2

IEPA Permit Log No. B-43R
Date of Last IEPA Letter on Project: Jan 18, 2017
Log No. of Last IEPA Letter on Project: B-43R-CA-59, -60, -69

Does this submittal include groundwater information: ☐ Yes ☑ No

Date of Submittal: April 6, 2017

5.0 Description of Submittal: (briefly describe what is being submitted and its purpose)

Site Characterization Summary (Part 1) and Tier 3 Proposal (Part 2) related to the SVE System for the project area in Roxana, Illinois. Copies separately sent to Jim Moore and Gina Search.

6.0 Documents Submitted (identify all documents in submittal, including cover letter; give dates of all documents)

Cover Letter dated April 6, 2017, RCRA Corrective Action Certification, TACO Tier 3 Demonstration Part 1: Site Characterization Summary, and TACO Tier 3 Demonstration Part 2: Tier 3 Proposal (2 copies submitted)

7.0 Certification Statement

(This statement is part of the overall certification being provided by the owner/operator, professional and laboratory in Items 7.1, 7.2 and 7.3 below). The activities described in the subject submittals have been carried out in accordance with procedures approved by Illinois EPA. I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

7.1 Owner/Operator Certification

(Must be completed for all submittals. Certification and signature requirements are set forth in 35 IAC 702.126.) All submittals pertaining to the corrective action requirements set forth in a RCRA Permit must be signed by the person designated below (or by a duly authorized representative of that person):

1. For a Corporation, by a principal executive officer of at least the level of vice president.
2. For a Partnership or Sole Proprietorship, by a general partner or the proprietor, respectively.
3. For a Governmental Entity, by either a principal executive officer or a ranking elected official.

A person is a duly authorized representative only if:

1. the authorization is made in writing by a person described above; and
2. the written authorization is provided with this submittal (a copy of a previously submitted authorization can be used).

Owner Signature: _____ Date: _____

Title: _____

Operator Signature: Kevin E Kleyer Date: 3/29/17

Title: Senior Principal Program Manager

7.2 Professional Certification (if necessary)

Work carried out in this submittal or the regulations may also be subject to other laws governing professional services, such as the Illinois Professional Land Surveyor Act of 1989, the Professional Engineering Practice Act of 1989, the Professional Geologist Licensing Act, and the Structural Engineering Licensing Act of 1989. No one is relieved from compliance with these laws and the regulations adopted pursuant to these laws. All work that falls within the scope and definitions of these laws must be performed in compliance with them. The Illinois EPA may refer any discovered violation of these laws to the appropriate regulating authority.

Any person who knowingly makes a false, fictitious, or fraudulent material statement, orally or in writing, to the Illinois EPA commits a Class 4 felony. A second or subsequent offense after conviction is a Class 3 felony. (415 ILCS 5/44 (h))

Executive Summary

On behalf of Equilon Enterprises LLC, d/b/a Shell Oil Products US (SOPUS), AECOM Technical Services, Inc. (AECOM) is submitting this Tiered Approach to Corrective Action Objectives (TACO) Tier 3 Demonstration ("Report"). The Report has been reviewed by Robert Ettinger of Geosyntec Consultants, Inc.

Since 2006, SOPUS, at the direction of the Illinois Environmental Protection Agency (IEPA), has been conducting subsurface investigations in the Village of Roxana in the area generally bounded by the alley north of East 1st Street (1st Street), the Roxana Public Works Yard, Illinois Route 111 (a/k/a South Central Avenue), and the property boundary ("West Fenceline") of the WRB Refining, LP (WRB)[1] Wood River Refinery (WRR) ("Investigation Area" or "the Site") and has operated soil vapor extraction (SVE) remediation in the vicinity of Chaffer Avenue along the West Fenceline since May 10, 2011. SOPUS' goal with this submittal is to present and obtain approval from the IEPA for site-specific Tier 3 remediation objectives (ROs) for soil gas. Based on a comparison of site data to the Tier 3 soil gas ROs, SOPUS recommends that the Regenerative Thermal Oxidizer (RTO) SVE system (SVE system) be turned off and a rebound monitoring program will be initiated. The results of the rebound monitoring will be used to assess if SOPUS' remedial efforts related to soil gas in this area are complete.

The IEPA's TACO rules (35 Illinois Administrative Code [IAC] 742) present procedures for developing soil gas remediation objectives under Tier 2 including using the Johnson & Ettinger (J&E) model. Under the Tier 2 assessment, TACO requires that institutional controls be implemented requiring future buildings are constructed with "*a full concrete slab-on-grade or a full concrete basement floor and walls*" (Section 742.1000(a)(9)). The Tier 3 ROs developed have been calculated assuming that a concrete slab-on-grade or full-concrete basement floor and walls are not present so that the institutional controls required under a Tier 2 assessment are not needed. The Little, Daisey, Nazaroff model (Little, et al., 1992) was used to develop the Tier 3 ROs. This model, hereafter referred to as LDN, is applied to buildings without concrete slabs or concrete basements.

Data presented in Part 1 of this Report support the conclusion that biodegradation of hydrocarbon vapors is occurring at the Site. However, the proposed Tier 3 ROs do not account for the effects of biodegradation on the migration of petroleum compounds in the vadose zone which incorporates added conservatism to the assessment.

Data presented in this Report demonstrate that soil gas has been remediated through the intermediate zone (e.g., to a depth of 20 feet below ground surface (bgs)). Soil gas data were compared to the proposed Tier 3 ROs within the shallow zone (e.g., to a depth of 10 feet bgs) and current soil gas concentrations meet the proposed ROs in the residential and construction worker areas[2]. Higher concentrations have been detected in samples collected at depth (e.g., below 20 feet) in certain areas; however, shallow data collected at these locations show that attenuation mechanisms decrease concentrations to below the objectives at shallow depths and the vapor intrusion (VI) pathway is not complete.

Since the site data meet the Tier 3 ROs, SOPUS proposes to shut down active SVE operations and begin a one year rebound monitoring demonstration period. The rebound monitoring program includes triggers for increased monitoring and restart of the SVE system should conditions change.

This document is presented in two parts for ease of review:

Part 1- Site Characterization Summary, presents an overview of site history and past investigations, site geology and hydrogeology, the nature and extent of petroleum hydrocarbons (PHC) in soil, soil gas and indoor air, as well as temporal changes in soil gas since the startup of the SVE system. Part 1 also presents a conceptual site model (CSM) for both pre-SVE and conditions based on data through 4th quarter 2016 (4Q16) presented in the Site Characterization Summary. The

[1] WRB, formed January 1, 2007, is a 50/50 joint venture between ConocoPhillips (COP) and EnCana US Refineries, LLC (now known as Cenovus Energy, Inc.). ConocoPhillips Company announced the separation of the Refining and Marketing business from the Exploration and Production business on July 14, 2011. The separation included an ownership change as well as a name change that became effective May 1, 2012. Phillips 66 is now the operator of the WRB WRR.

[2] With two outliers which are discussed in **Section 2.2.1** of **Part 2** of the Tier 3 Demonstration.

presentation of temporal data provides evidence of the effectiveness of the SVE system in remediating soil gas and supports the development of a path forward to permanent SVE system shutdown and dismantlement. Supporting tables, figures, and appendices are included.

Part 2- Tier 3 Proposal, begins with a summary of the key site characterization conclusions from Part 1, then introduces the J&E and LDN models and the overall mass flux model approach to calculating soil gas concentration end points that are protective of indoor and trench air. Part 2 discusses the inputs used to calculate the LDN model values and presents the modeling results. Based on the results of the LDN modeling, Tier 3 remediation objectives are proposed. Using the proposed remediation objectives, Part 2 outlines suggested system shutdown and a rebound monitoring program.

1 Introduction and Site History

SOPUS' remedial strategy for the affected portions of the Village of Roxana and the West Fenceline portion of the WRR consists of LNAPL recovery, and groundwater gradient control and mitigation of soil gas vapors within the Village of Roxana west of the WRR. These elements are briefly described below.

- **Groundwater Containment and Treatment**

  Active containment and treatment of impacted groundwater has been and continues to be achieved through operation of a network of groundwater production wells located on the North and Main Properties of the WRR. The groundwater pumping creates a broad cone of depression (capture zone) that extends into portions of the Village of Roxana, with horizontal gradients directed inward toward the interior of the North Property. Recovered groundwater is partially utilized for non-contact cooling water and fire water. After use, excess recovered groundwater is treated in the refinery's wastewater treatment plant (WWTP) and discharged under a National Pollutant Discharge Elimination System (NPDES) permit.

- **Source Removal**

  The WRR groundwater production wells remove hydrocarbon mass in the dissolved phase along with incidental amounts of light non-aqueous phase liquid (LNAPL). A LNAPL recovery system that is comprised of recovery wells with total fluids pumps operates adjacent to most of the groundwater production wells. The recovered groundwater and LNAPL is separated and the LNAPL is reprocessed in the Distilling Unit and groundwater is treated at the refinery's WWTP.

- **Soil Vapor Extraction**

  The SVE system was designed and constructed along the West Fenceline of the WRR North Property and within the Public Works Yard to address hydrocarbon vapors in the Village. The West Fenceline portion of the SVE system began operation on January 31, 2012; additional wells have been added since then. The Public Works Yard section came online December 6, 2012. The current system consists of 45 SVE wells, 31 of which are located in the WRR along the West Fenceline, nine are located on three properties near the intersection of East 4th Street (4th Street) and Chaffer Avenue, and six are located in the Roxana Public Works Yard. Collected vapors are treated with a RTO located within the WRR North Property.

The efficacy of each of these elements is measured by separate monitoring programs. Groundwater and LNAPL management is discussed in SOPUS' Groundwater Management Zone (GMZ) Proposal, submitted in May 2016 (currently pending IEPA review/approval). The GMZ was prepared as requested by the IEPA in their letter to SOPUS dated February 23, 2016 in which the IEPA agreed with the conclusion

n that groundwater within the Village of Roxana has been delineated (IEPA, 2016). Therefore, this Tier 3 Demonstration addresses soil gas and the SVE system.

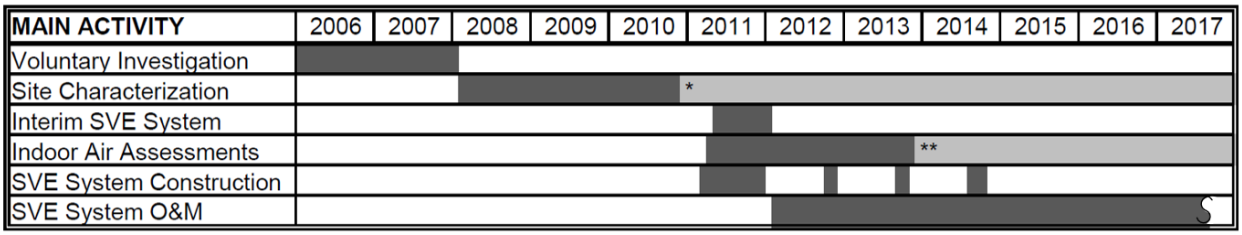
1.1 Site History and Past Investigations

SOPUS has been conducting subsurface investigations in the Village of Roxana ("Village") in the area generally bounded by the alley north of 1st Street, the Roxana Public Works Yard, Illinois Route 111, and the property boundary (a/k/a West Fenceline) of the WRB WRR (**Figure 1-1**) since 2006. This Site history section provides an overview of the major milestone events related to characterization and remediation of soil and soil gas[3] including key investigations, reports, and remedial activities.

[3] The term soil gas is used interchangeably with soil vapor throughout the report. The term "soil vapor" is generally used when descr bing an established program such as "Quarterly Soil Vapor Monitoring Program".

SOPUS retained AECOM (formerly URS Corporation (URS)) to perform remedial activities and reporting described chronologically in the Investigations and Reports Section below[4]. In addition, a graphical representation of major milestones is depicted in **Exhibit 1-1** below.

Exhibit 1-1: Main Activity



* = Sporadic data collection for focused objectives.
** = Performed if requested by home owner.

Investigations and Reports

2006 - 2008

The *West Fenceline P-93 Dissolved Phase Benzene Investigation Work Plan* (URS, 2006) was prepared due to increases in benzene concentrations in groundwater observed in 2005 during regular groundwater monitoring activities onsite at the refinery along the West Fenceline (URS, 2007). The results of this investigation included recommendations for additional investigative activities including evaluation of soil and soil gas.

A work plan for additional investigation in the vicinity of Route 111/Rand Avenue was prepared to gather data to refine the conceptual site model, evaluate potentially complete exposure pathways, and develop remedial options (URS, 2008). IEPA provided approval of, and comments on, this work plan in a letter dated November 25, 2008 (IEPA, 2008).

2009 - 2010

The soil and soil gas results of the additional investigative work performed in 2008 were presented in a report submitted to the IEPA on January 21, 2009[5] (URS, 2009a). Key conclusions presented in the report included the following:

- Soil samples generally exhibited the highest petroleum concentrations in samples between depths of 14 and 24 feet bgs, which is within clayey soils and indicative of residual hydrocarbons sorbed to the fine grained soils.
- Soil gas results collected from locations overlying the highest observed groundwater concentrations showed relatively low and sporadic benzene, toluene, ethylbenzene, and xylenes (BTEX) concentrations.

The *Dissolved Phase Groundwater Investigation and P-60 Free Phase Product Delineation Work Plan* was developed based on those conclusions, conversations with the IEPA, and SOPUS' Compliance Commitment Agreement related to a Violation Notice. The primary objectives were to assess the nature and extent of the mixed hydrocarbons identified along the WRR's West Fenceline and to further delineate the extent of impact near well P-60 (URS, 2009b).

On May 12, 2009, the IEPA provided a letter to SOPUS approving the 2009 *Dissolved Phase Investigation and P-60 Free Phase Product Delineation Work Plan* with conditions and modifications (IEPA, 2009). The results of this investigation were submitted to IEPA on February 18, 2010 (URS, 2010a) with recommendations for additional investigative work.

The IEPA provided comments on the report in a letter dated August 5, 2010 (IEPA, 2010a), which requested that existing soil gas monitoring points be sampled on a quarterly basis starting with the 3rd Quarter 2010 (3Q10) sampling event. The samples were to be analyzed for benzene, hexane, and other petroleum hydrocarbons using a modified U.S. Environmental Protection

[4] This section summarizes significant investigations, reports, and correspondence focusing on soil and soil vapor in the Village of Roxana.

[5] An initial version of the report was submitted to the IEPA in August 2008. The report was revised to incorporate comments provided by IEPA in a November 25, 2008 letter (IEPA, 2008). The revised report was submitted to the IEPA on January 21, 2009.

Agency (USEPA) Method TO-15 or similar analysis. The August 5, 2010 letter also requested that six additional vapor monitoring points (VMPs) be installed to determine the extent of the soil gas containing petroleum impact; see **Figure 1-2** for VMP locations and installation dates). The six additional VMPs were added to the program as of 1st Quarter 2011 (1Q11)[6].

An addendum to the February 18, 2010 report was submitted to the IEPA on September 20, 2010 (URS, 2010c) which included investigative activities requested in IEPA's August 5, 2010 letter. The results of this supplemental investigation complemented the results collected during the 2009 investigation.

The August 5, 2010 letter from the IEPA also required the (consecutive) submission of the following:

- Work plan to evaluate possible VI into residences, to collect sub-slab and indoor air samples, and offer interim measures to protect residence where elevated sub-slab hydrocarbons were detected, if any (Condition 4).
- Conceptual Design Report for additional corrective measures to address hydrocarbons detected along West Fenceline of the North Property (Condition 15).

The *Vapor Intrusion Investigation Work Plan* was originally submitted on September 20, 2010 (URS, 2010d), to which the IEPA provided comments to SOPUS in a letter dated November 15, 2010 (IEPA, 2010b).

2011

Scoping meetings were held with representatives of IEPA, Illinois Department of Public Health (IDPH), and Village of Roxana (Agencies), as well as SOPUS, and URS on January 6, 2011 and January 25, 2011. In addition, there was various email correspondence associated with scoping for the project. Relevant information from these communications was incorporated into a revised *Vapor Intrusion Investigation Work Plan*, which was resubmitted on March 29, 2011 (URS, 2011a).

IEPA provided approval of and comments on this work plan in a letter dated April 6, 2011 (IEPA, 2011b). The approach included evaluating potential vapor intrusion via vapor screening and sampling in structures and suggested installation and operation of a SVE system along the West Fenceline and in the Public Works Yard. Indoor air and sub-slab sampling was performed as approved in the 2011 *Vapor Intrusion Investigation Work Plan*. The results of these investigations were provided to each respective resident and the Agencies. The results are presented in **Section 3.4**.

Installation and Operation of SVE system

2010 - 2011

As a result of the vapor intrusion investigations, SOPUS proposed installation of a SVE system, pending the performance of a SVE pilot test. In December 2010, SOPUS submitted a *SVE Pilot Test Work Plan* to IEPA (URS, 2010b). The *SVE Pilot Test Work Plan* was formally approved by IEPA on March 16, 2011 (IEPA, 2011a). The SVE Pilot Test was conducted from February 28, 2011 through March 24, 2011[7] and consisted of two separate scopes of work:

1. Conduct soil vapor extraction to determine the radius of influence (ROI) for well spacing, extraction rates and pressures for blower design and vapor concentrations for treatment system design; and
2. Conducted a data gap investigation to better define the extent of impact in proximity to the West Fenceline.

The SVE pilot test consisted of a series of data collection activities at two SVE wells shown on **Figure 1-2**; SVE-1 (WRR Property) and SVE-2 (Public Works Yard). Pilot test activities consisted of applied vacuum generated through an internal combustion engine (ICE) unit increased in a step-wise fashion. The *SVE Pilot Test Report* (URS, 2011c) providing the results of this work was submitted to IEPA on July 19, 2011, which served as the basis for the SVE system design). Details regarding the SVE system design and layout are discussed in **Section 4.1**.

[6] URS on behalf of SOPUS submitted a letter on September 20, 2010 requesting an extension to certain conditions contained in the August 5, 2010 letter. This extension was approved with comments on November 15, 2010. Monitoring at the six newly installed VMPs commenced1Q11 (URS, 2010e).

[7] IEPA formally approved the pilot test work plan on March 16, 2011 (IEPA, 2011a); however, based on conversations with the IEPA, pilot test activities moved forward ahead of formal approval.

The *Conceptual/Final Design Report* required by both the August 5, 2010 and March 16, 2011 IEPA letters was submitted to the IEPA on June 10, 2011 (URS, 2011b). The SVE system was the proposed primary remedial technology. Other technologies were also considered (such as recovery of LNAPL through a skimming system, air sparge, thermal treatment, and in-situ chemical oxidation); however, for varying reasons, these technologies were not chosen for the system design (URS, 2011b). Initial SVE system design consisted of installation of twenty-eight SVE wells along the West Fenceline, six SVE wells in the Public Works Yard (**Figure 1-2**), vapor extraction components, and RTO, connected via carbon steel conveyance piping routed atop concrete supporting piers[8].

Several interim measures were undertaken while the SVE system was being installed. The use of temporary ICE units to mitigate affected soil gas around the East 4th Street and Chaffer Avenue area began on May 13, 2011, with the installation and operation of a single engine ICE unit. An additional dual engine ICE unit began operation on June 16, 2011. The ICE units were connected to wells SVE-3, SVE-4, and SVE-25, located in 4th Street near Chaffer Avenue. VMP-31 and VMP-32 were also installed and monitored on a bi-weekly basis, along with VMP-3, VMP-4, and VMP-43, to observe the influence and effectiveness of the ICE units during the interim measures period. Operation of the ICE units was considered the Interim SVE system.

2012

The ICE units were decommissioned on January 31, 2012, after startup of the SVE system. The interim measures implemented prior to the startup of the SVE system successfully reduced petroleum vapors beneath the affected structures based on the observed decrease in sub-slab soil gas concentrations.

Installation and startup of the West Fenceline portion of the SVE system was completed between March 2011 and January 2012. A *Construction Completion Report* for the West Fenceline portion of the system was submitted to the IEPA on May 30, 2012 (URS, 2012). At the time of installation of the West Fenceline portion of the SVE system, access to the Village property, including the Public Works Yard, had not yet been provided to SOPUS. An access agreement between SOPUS and the Village was executed on October 5, 2012, after which the Public Works portion of the SVE system was installed and connected. (A *Construction Completion Report Addendum* specific to the installation and connection of the six SVE wells located in the Public Works Yard was submitted to the IEPA on February 14, 2013 (URS, 2013a)).

In a letter dated September 13, 2012, IEPA provided a response to several submittals made by SOPUS regarding investigation and remediation efforts to address contamination present along/near the West Fenceline (IEPA, 2012). The September 13, 2012 letter included approval of the design and partial construction (as the letter was provided after construction activities began) per the 2011 *Conceptual/Final Design Report*. Several key conditions from the September 13, 2012 letter are outlined below.

- Condition 6 required that the initial system be expanded, if necessary, if the design did not appear to be adequately removing the contaminated soil gas from the subsurface within the investigation area.
- Condition 7 outlined the system data to be collected to ensure the system was properly operating. This system data is included as part of the Quarterly Soil Vapor Reports.
- Condition 9 requested that SOPUS install nine additional VMPs (VMP-47 through VMP-55) and identified the approximate locations and screen intervals for the additional VMPs. These VMPs were installed in December 2012.
- Condition 11 outlined effectiveness monitoring procedures required on a monthly basis to monitor the general operational effectiveness of the SVE system. This program is referred to as “Effectiveness Monitoring”. The Effectiveness Monitoring program continues to be performed as of the date of this Report and is described in **Section 4.1**. The data collected as part of the Effectiveness Monitoring program is submitted as part of the Quarterly Soil Vapor Monitoring Reports.

2013 - 2015

In August 2013, based on the results of the data collected during monthly Effectiveness Monitoring and quarterly soil gas sampling, SOPUS decided to extend the West Fenceline portion of the SVE system to the north to address soil gas

[8] Construction deviations relative to the Conceptual/Final Design Report were discussed in the Construction Completion Report submitted to the IEPA on May 30, 2012 (URS, 2012).

concentrations observed in and around VMP-47. The West Fenceline extension included the installation of five additional SVE wells (SVE-37 through SVE-41) and four additional VMP locations (VMP-57 through VMP-61). *Construction Completion Report Addendum 2* was submitted to IEPA on January 9, 2014, documenting the West Fenceline system extension (URS, 2014a).

To further evaluate remedial options, an *Air Sparging (AS) and Soil Vapor Extraction Pilot Test Work Plan* was prepared and submitted to the IEPA on August 16, 2013 (URS, 2013b). This pilot test was performed in December 2013 to evaluate the viability of AS coupled with an extension of the SVE system to enhance the performance of the existing SVE system in the vicinity of 4th Street and Chaffer Avenue. The results of this pilot test indicated that the geology of the proposed test area would impede sufficient recovery of sparge air; therefore, the AS technology was not pursued.

However, based on data collected during the AS Pilot Test, SOPUS decided to move forward with the installation of additional SVE wells and extend the existing SVE system onto the vacant, SOPUS-owned 4th Street properties. A conceptual design for this extension was developed and presented in the *Conceptual Design, SVE System Extension, 4th and Chaffer Avenue (Conceptual Design) Report*, dated July 2014 (URS, 2014b).

The 4th Street extension of the SVE system, detailed in the 2014 Conceptual Design, recommended that six additional SVE wells (SVE-42 through SVE-47) be installed on the SOPUS-owned properties. The location of each SVE well was selected based on evaluation of cone penetration test (CPT) and Rapid Optical Screening Tool (ROST™) data gathered from borings installed on the Shell-owned property[9] (AECOM, 2015b). In addition, soil gas screening data, soil gas laboratory analytical data, and system vacuum data collected monthly from VMPs located in the vicinity of the properties were used to assist in determining the locations of the proposed SVE wells. These SVE wells were installed between July 29, 2014, and August 19, 2014 and *Construction Completion Report Addendum 3* was submitted to the IEPA on March 4, 2015, documenting the extension (AECOM, 2015a).

Monitoring and Operations

The SVE system is operated in accordance with the SVE Operation and Maintenance (O&M) Plan dated February 2016 (AECOM, 2016b). Since SVE system start up on January 31, 2012, the SVE wells and RTO have operated continuously, with short periods of down time due to scheduled maintenance or unscheduled events such as power outages. SVE wells are closed as areas are remediated and a period of rebound monitoring is subsequently initiated in the area of the closed well.

The quarterly sampling requested in the August 5, 2010 letter from the IEPA continues to be performed as of the date of this Report and has been expanded to include additional VMPs that have been installed since 2010 (as required by IEPA). Quarterly Soil Vapor Monitoring Reports have been provided for each quarter since 3Q10. Subsequent correspondence between IEPA and SOPUS have modified reporting requirements; however, the program has remained generally consistent since its inception. The effectiveness of the SVE system, in removing petroleum hydrocarbons from the subsurface, which is described in subsequent sections of this Report, has prompted the development of the proposed Tier 3 remediation objectives presented in Part 2 of the Tier 3 Demonstration.

1.2 Community Relations

A Community Relations Plan (CRP), dated February 9, 2009, was developed in response to a letter from the IEPA to SOPUS dated June 13, 2008, and supplemented in an August 19, 2008 correspondence (URS, 2009c). The CRP provides information outlined in the “Right-to-Know” regulations (35 IAC Part 1600). The main components of the CRP include maintaining a repository accessible via internet (http://roxanainvestigation.urs-stl.net) (Roxana Website) as well as a local repository at the Roxana Village Hall. Additionally, several notifications and fact sheets have been prepared and provided to keep residents informed of site conditions and activities, primarily focusing on the SVE system. Fact sheets, reports, work plans, and various correspondences described in **Section 1.1** of this Report can be viewed on the Roxana Website.

[9] CPT and ROST™ borings were installed in May 2013.

2 Site Setting

The Site and surrounding area are located within the Mississippi River flood plain in the northernmost extension of an area known as the American Bottoms. The surface topography is generally flat with surface elevations range from approximately 420 to 450 feet (relative to 1988 North America Vertical Datum [NAVD]). The ground surface in the Village, where not developed with structures, is primarily grass covered with paved (i.e., chip and seal, asphalt, etc.) alleys and streets.

2.1 Geology

2.1.1 Regional Geology

Over geologic time, the Mississippi River has meandered over its floodplain, depositing various layers of fine and coarse material. This has resulted in alluvial deposits consisting of a complex, heterogeneous sequence of interbedded gravels, sands, silts, and clays throughout the floodplain. This alluvial valley fill in the vicinity of the Site has a thickness ranging from 100 to 170 feet, composed mostly of recent alluvium overlying glacial outwash material. The permeable sands and gravels in the unconsolidated valley fill provide a large resource of groundwater. Subsurface conditions underlying the Site generally consist of two primary strata: (1) a layer of shallow silty clay and (2) an underlying layer of sands with occasional interbedded silt or clay layers. The underlying glacial outwash deposits consist of more uniform sands and gravels that extend to bedrock. These alluvial and glacial materials overlie Mississippian and Pennsylvanian Age bedrock, primarily limestone and dolomite, interbedded with lesser amounts of sandstone and shale. The depth to bedrock typically ranges from 100 to as much as 170 feet bgs.

2.1.2 Site Geology

The subsurface stratigraphy at the Site was investigated by completing soil borings and CPT probes at the locations shown on **Figure 2-1**. Subsurface stratigraphy described above within the Site area generally consists of the following materials, from the ground surface down:

- Fill – The fill consists mainly of clay with varying amounts of gravel, cinders, brick, etc. The fill typically extends from the ground surface to approximately six feet bgs.
- Clay/Silt – The clay is primarily a low to medium plastic, silty clay. Where present, the clay generally extends from the base of the fill to as deep as approximately 25 feet bgs.
- Sand – The sand is primarily of fine to medium grained, which coarsens with depth and is mixed with gravels at depth. At shallower depth, silt and clay lenses may be present in localized areas. The sand begins at the base of the clay (or base of the fill if the clay is not present) and extends to the bedrock surface.

Within the sand layer, discontinuous lower permeability lenses of clay with some silt and sandy silt are occasionally present. These lenses vary in thickness from approximately one inch to a few feet and do not appear to be laterally or vertically extensive or continuous throughout the Investigation Area. They are most prevalent immediately east and west of Chaffer Avenue bounded by East 3rd Street (3rd Street) to the north and East 6th Street (6th Street) to the south. Geologic cross-sections depicting typical subsurface conditions at the Site are provided in **Figure 2-2** through **Figure 2-4**.

Additional details on the subsurface conditions at the Site can be viewed on boring logs and CPT logs provided in **Appendix 2-A** and **Appendix 2-B**, respectively. A summary of known sub-surface utilities is provided in **Table 2-1**.

2.2 Hydrogeology

2.2.1 Regional Hydrogeology

The sands and gravels in the unconsolidated valley fill of the American Bottoms Aquifer are relatively permeable and contain significant amounts of groundwater. The depth to groundwater within the aquifer is typically measured at approximately 25 to 40 feet bgs, resulting in a 15 to 30 foot thick vadose (unsaturated) zone within the unconsolidated deposits. This groundwater system is hydraulically connected to the Mississippi River. The bedrock underlying the unconsolidated valley fill has a much lower permeability and contains limited amounts of groundwater.

2.2.2 Site Hydrogeology

The typical current elevation of groundwater within the groundwater monitoring wells located throughout the Site is approximately elevation of 400 to 405 feet NAVD. In general, water levels rose since approximately 2007, reaching a maximum elevation in 2011. Groundwater elevations declined from 2011 to 2014 and began increasing through 2016. Due to this rise in groundwater elevation, most of the groundwater monitoring well screens have been submerged during many quarterly gauging events performed over the last nine years.

Groundwater at the Site and surrounding area is recharged by precipitation and surface water infiltration from bodies of water within the vicinity. Though the groundwater is hydraulically connected with the Mississippi River, given the large distance (approximately 1.5 miles) from the river, water level fluctuations due to river rise take longer to occur, and the magnitude of the fluctuations are muted in comparison to observations at locations closer to the river. In addition, high volume pumping of groundwater at the WRR facility is a significant controlling factor on groundwater levels and flow direction at the Site. The pumping of water from wells near the West Fenceline and interior water production wells contributes to the creation of a cone of depression beneath the refinery, which provides a locally inward gradient of groundwater flow toward the WRR from the Site.

3 Nature and Extent of Petroleum Hydrocarbons

This section presents an overview of the nature and extent of petroleum hydrocarbons for soil, soil gas, and indoor air based on data that has been collected at the Site through 4Q16.

3.1 Site Sampling Overview

Since 2008, a substantial number of indoor air, soil gas, and soil samples have been collected at the Site to characterize the nature and extent of petroleum hydrocarbon impact within soil and soil gas. The samples have been collected in connection with several Site investigations as well as routine monitoring programs.

The laboratory analytical samples collected at the Site through 4Q16 include over 200 indoor air samples, over 330 soil samples, and over 3,400 soil gas samples. In addition to the samples that were collected for laboratory analysis, over 17,000 soil gas samples have been collected and field-screened since 2008.

The large amount of data collected from the Site, particularly the amount of soil gas data collected during routine monthly and quarterly monitoring events, supports a strong basis of understanding of the subsurface conditions at the Site. An overview of the results of these sampling efforts is provided in **Sections 3.2**, **3.3**, and **3.4**.

3.1.1 Sampling and Analytical Procedures

Investigation work plans and monitoring plans, including sampling, analytical, and quality assurance/quality control (QA/QC) protocols, were prepared prior to sample collection. QA/QC protocols were implemented to ensure that the data are of sufficient quality to meet the investigation and monitoring objectives.

For soil samples, QA/QC protocols included collection of equipment blanks (EBs), duplicates (DUPs), and matrix spike/matrix spike duplicate (MS/MSD) samples, which were submitted to the laboratory for analysis. For soil gas and indoor air samples, QA/QC protocols included collection of DUPs, which were submitted to the laboratory for analysis. A completed sample label was attached to each sample container. The labels included the project name and number, sample identification, initials of the sampler(s), sampling location, required analysis, date and time of sample collection, pre- and post-vacuum readings (for soil gas samples), and preservative used, if any (for soil samples). Upon collection and labeling, soil sample containers were immediately placed inside an iced cooler and packed in such a way as to help prevent breakage and maintain inside temperature at or below approximately 4ºC, when required. Soil gas and indoor air samples were packaged in an UN-certified box to prevent damage to sample media during shipment.

Field personnel recorded the sample identification, sample description/location, required analysis, date and time of sample collection, type and matrix of sample, number of sample containers, preservative used (if applicable), analysis requested/comments, and sampler signature/date/time, with permanent ink on the chain-of-custody (COC). Prior to shipment of soil samples, coolers were sealed between the lid and sides of the cooler with a custody seal, and then shipped to an analytical laboratory via overnight courier. Trip blanks were included with each shipment of soil samples planned for volatile organic compound (VOC) analysis. Prior to shipment of soil gas and indoor air samples, boxes were sealed with tape and a custody seal over the top, and then shipped to an analytical laboratory via overnight courier. Due to the potential flammable nature of the vapor in the soil gas canisters, some soil gas and indoor air samples were shipped as hazardous materials according to applicable regulations.

AECOM works with laboratories to attain reporting limits for compounds that have screening criteria so that, to the extent possible, the reporting limits were less than the screening criteria. In some cases, this necessitated reporting results between the method detection limit (MDL) and reporting limit (RL). Although results reported in this range are "J"-flagged as estimated concentrations by the laboratory, these data may be beneficial in cases where analytes would otherwise be reported as non-detect at RLs above screening levels.

Laboratory data were provided in electronic form, and analytical data were independently reviewed and qualified by AECOM. One hundred percent of the data were subjected to a data quality review. Evaluation of the data followed procedures outlined in the USEPA National Functional Guidelines for Superfund Organic Methods Data Review (USEPA, 2008 and USEPA, 2014). Specific criteria reviewed included sample receipt condition and holding times, method blanks, surrogate spike recoveries, laboratory control samples, results reported from dilutions, and field duplicate results. The laboratory assigned data qualifiers on the basis of their quality control or to indicate sample analysis information (e.g., dilutions). Data qualifiers were also added by AECOM, as appropriate, and are included on the data tables and laboratory result pages. Laboratory reports are stored in the project files and were provided as part of the reports submitted to IEPA, as required.

3.2 Soil

Lithologic data and soil samples for laboratory analysis have been collected in conjunction with other targeted subsurface investigations (i.e., soil gas and groundwater investigations) at the Site as requested by IEPA and summarized in **Section 1.1** of this Report. Subsurface investigative methods have included hollow stem auger (HSA) drilling, roto-sonic drilling, direct push technology (DPT) borings, hand auger soil borings, and CPT/ROST™ soil probes. Soil samples were collected between May 2008 and October 2015.

Soil Sampling Overview

Prior to conducting investigative activities, scope and location specific access agreements were issued by the Village. Boring locations were marked in the field (e.g., with spray paint or stakes). A utility locate was arranged using Illinois's Joint Utility Locating Information for Excavators (JULIE) service. Additionally, a private utility locating service was contracted to identify private utility lines and confirm the presence of potential underground lines as marked by JULIE. The Roxana Public Works Department also reviewed the locations and provided relevant information concerning their utilities in the area.

Vacuum excavation ("air-knifing") was used to clear all borehole locations with respect to underground utility lines or other obstructions. The specific target depths of the air-knife holes were determined based upon a review of the subsurface utilities in the area with input from the Village, as appropriate, and were typically 10 feet bgs. Grab soil samples were typically collected via hand auger throughout the depth of the air-knifed hole to document lithology. Cleared locations were backfilled with clean sand and covered with a metal plate if drilling activities were not immediately commenced.

Soil borings were continuously advanced at each location to log lithology and collect representative soil samples. Subsurface stratigraphy was logged in accordance with applicable American Society for Testing and Materials (ASTM) standards, Unified Soil Classification System (USCS) protocols and applicable URS or AECOM procedures. Noted soil attributes included color, particle size, consistency, moisture content, structure, plasticity, odor (if any), and organic content (if visible). Soil samples from each boring were visually evaluated for evidence of hydrocarbon impact and screened in the field using a photoionization detector (PID), typically at 1- to 2-foot intervals. Subsurface lithologic information, PID screen results, and other observations are presented in the soil boring logs (**Appendix 2-A**).

Soil samples were collected from the majority of soil borings and submitted for laboratory analysis. Up to three soil samples were typically collected from each boring. Soil samples were typically collected from near the top of the boring, the interval with the highest PID reading or visual/olfactory indications of impact within the length of the boring, immediately above the groundwater surface, and/or from within the screened interval of the proposed location. Most of the boreholes installed were converted into VMPs, SVE wells, or groundwater monitoring wells.

Various analytical laboratories have been used for sample analysis throughout the duration of this project. Xenco Laboratories of Stafford, Texas conducted laboratory testing on soil samples from January 2008 through December 2010. Accutest Laboratories New England of Marlborough, Massachusetts conducted laboratory testing on soil samples from January 2011 through October 2015. TestAmerica Laboratories, Inc. of Pensacola, Florida conducted testing on soil samples from October 2015 to the present. Testing was conducted for requested combinations of up to the following parameters:

- VOCs via USEPA Method 8260 or USEPA Methods 8260 and 8011;
- Total Petroleum Hydrocarbons (TPH), C6-C10 range and/or C10-C28, C28-C40 ranges via EPA Method 8015; and/or
- Semi-Volatile Organic Compounds/Polycyclic Aromatic Hydrocarbons (SVOCs/PAHs) via EPA Method 8270/EPA Method 8270 Low Level.

A total of 42 CPT/ROST™ probes were also completed at the Site to provide additional information on geological conditions as well as a broad characterization on the nature and extent of hydrocarbon impact to soil beneath the Site. Utility clearance and air knifing activities were completed at CPT/ROST™ locations in a manner consistent with other soil boring locations.

The CPT/ROST™ probes were completed by hydraulically pushing a cone, equipped with a pore pressure transducer, through the soil at a consistent rate of two centimeters (cm) per second. The cone has a tip cross-sectional area of 15 cm^2 and the friction sleeve area of 200 cm^2. Measurements were collected for resistance to penetration, sleeve friction, and pore pressure once per second during advancement of each probe hole. These measurements provided soil property data, which were converted to a stratigraphic profile for each probe hole. CPT logs are provided in **Appendix 2-B**.

ROST™ technology was used in conjunction with the CPT at each of the 42 probe locations completed at the Site. The ROST™ system used at the Site consisted of a tunable laser mounted in a CPT rig connected to a down-hole sensor. The down-hole sensor consisted of a small diameter sapphire window mounted flush with the side of a CPT probe. The down-hole ROST™ sensor was deployed utilizing standard CPT technology as described above.

As the ROST™ sensor was hydraulically advanced, the laser and associated equipment transmitted 50 pulses of light per second to the sensor through a fiber optic cable. The wavelength of the pulsed excitation light could be set to wavelengths between 280 and 300 nanometers (nm). An excitation wavelength of 290 nm (i.e., Site specific) was used for each test during this project. The laser light was transmitted through the sapphire window and was absorbed by aromatic hydrocarbon molecules in contact with the window. This addition of energy (photons) to the aromatic hydrocarbons caused them to fluoresce. A portion of the fluorescence emitted from any encountered aromatic constituents was returned through the sapphire window and conveyed by a second fiber optic cable to a detection system within the CPT rig. The emission data resulting from the pulsed laser light was averaged into one reading per one second interval (approximately one reading per two cm vertical interval) and recorded continuously. Based on the returned fluorescence wavelength and intensity, likely hydrocarbon type and percent fluorescence within the subsurface were determined. ROST™ logs can be viewed in **Appendix 3-A**. Upon completion, CPT/ROST™ probe holes were backfilled with grout and completed to match the surrounding ground surface.

Soil Investigation Results Summary

The laboratory analytical results for soil samples collected at the Site are provided in **Appendix 3-B**, Summary of Soil Analytical Data. The laboratory analytical results, CPT/ROST™ data, and subsurface geologic information gathered from soil borings were used to determine the nature and extent of petroleum hydrocarbon impact to subsurface soils at the Site.

In the soil samples collected at the site (over 330) one or more BTEX constituents were detected in 61-65 percent of the samples analyzed by the laboratory. BTEX constituents are considered to be the most representative indicators of soil impact at the Site and, as such, are presented throughout this Report.

The distribution of pre-SVE system petroleum hydrocarbons in soil is depicted on the cross-sections on **Figures 3-1** and **3-2**. **Figure 3-1** consists of a north to south cross-section along Chaffer Avenue and a west to east cross-section along 4th Street depicting PID concentrations (ppm) in soil prior to SVE installation. **Figure 3-2** presents the same cross-sections depicting BTEX concentrations (mg/kg) in soil prior to SVE installation. All cross-section concentration contour data were generated using CTech™ Environmental Visualization Software (EVS). Concentrations between known data points are interpolations and extrapolations of measured data. The bottom of the model represents an average potentiometric groundwater surface for the monitoring period.

These figures show the vertical and horizontal distribution of PID readings, and BTEX in soil in portions of the Site. Taken together in conjunction with the subsurface geology cross sections (**Figure 2-2** through **Figure 2-4**), the soil data indicate the following:

- Based on PID screening and laboratory analysis of soil samples, aromatic petroleum hydrocarbon impact existed in the vicinity of 4th Street and East 5th Street (5th Street) prior to SVE system installation and operation.
- Prior to SVE system installation, as shown on **Figure 3-1** and **Figure 3-2**, aromatic petroleum hydrocarbons existed in silt and clay layers at intermediate depths (10 to 20 feet bgs) in the vadose zone beneath limited portions of the Site adjacent to Chaffer Avenue. The highest concentrations of petroleum hydrocarbons were present in the soil samples analyzed in a localized area near 4th Street.
- As depicted on **Figures 3-1** and **3-2**, aromatic petroleum hydrocarbons exist in deep soils (approximately 30 to 50 feet bgs) in the soil samples analyzed in portions of the Site adjacent to Chaffer Avenue and within the soil samples analyzed adjacent to the Public Works Yard portion of the Site.

3.3 Soil Gas

SOPUS has been investigating and delineating soil gas in the Investigation Area through the installation, development, and quarterly analytical sampling of VMPs. VMPs sampled during quarterly monitoring events were installed based on correspondence with the IEPA as described below.

- VMP-1 through VMP-16 were installed in July and August 2009 based on a work plan submitted to IEPA on January 21, 2009 (URS, 2009b). Due to the presence of elevated soil gas concentrations, SOPUS operated a temporary SVE system from May 10, 2011 until January 31, 2012 when a completed SVE system was turned on. Refer to **Section 4** for further discussion on SVE system design and operation.

- VMP-17 though VMP-19 and an additional port at VMP-3 were installed in the Spring/Summer 2010 based on recommendations from the Dissolved Phase Groundwater Investigation and P-60 Free Phase Product Delineation Report, dated February 18, 2010 (URS, 2010a).

- VMP-20 through VMP-25 were installed in 1Q11 based on comments from IEPA in a letter to SOPUS dated August 5, 2010 (IEPA, 2010a).

- VMP-31, VMP-32 and VMP-42 through VMP-45 were installed as a result of a meeting between SOPUS and the IEPA on February 8, 2012. VMP-31 and VMP-32 were installed in 2nd Quarter 2011 (2Q11) to monitor soil gas during operation of the ICE unit located near 4th Street and Chaffer Avenue. VMP-42 through VMP-45 were installed during the 3rd Quarter 2011 (3Q11) and 4th Quarter 2011 (4Q11) in conjunction with the SVE system installation to monitor soil gas concentrations.

- VMP-29, VMP-30 and VMP-41 were installed based on a September 13, 2012 letter from the IEPA (IEPA, 2012). These VMPs are located within the Roxana Public Works Yard.

- VMP-47 through VMP-55 were installed during the 4th Quarter 2012 (4Q12) in the Village.

- VMP-62 through VMP-64 were installed during the 4th Quarter 2013 (4Q13) in the Village based on recommendations from the Roxana Soil Vapor Delineation near VMP-47 Work Plan, dated September 13, 2013 (URS, 2013c).

- VMP-31 was abandoned and replaced in the quarterly sampling program by VMP-56[10] based on an April 9, 2014 letter from the IEPA (IEPA, 2014).

In addition to the VMPs listed above, numerous VMPs have been installed in the WRR to monitor SVE system effectiveness and are not monitored for analytical data on a quarterly basis. The complete soil gas sampling network, including VMPs only sampled during monthly SVE effectiveness events, currently consists of 63 VMP locations (**Figure 1-2**), of which 46 locations are currently being utilized for quarterly sampling. A summary of VMP screen depths is provided in **Table 3-1**.

[10] Data from VMP-31 indicated the integrity of some of the ports was compromised, and it was replaced with VMP-56.

Soil gas samples collected through January 31, 2012 are representative of subsurface petroleum hydrocarbon concentration prior to operation of the SVE system. Soil gas samples collected after January 31, 2012 were taken after startup of the SVE system.

Soil Gas Sampling Overview

Soil gas sampling activities were attempted at each required VMP location[11] within the Investigation Area during each quarterly monitoring event. The sampling was performed in accordance with Standard Operating Procedures (SOPs) developed in part using input provided by IEPA and ASTM D-7663-12.

The following steps were used to collect each VMP sample:

- Upon arrival at a sampling location, the sampling crew would open the vapor port vault to visually check integrity of each individual VMP.
- The sample train was set up and connected directly to the monitoring port using compression ferrule connections. Each flow controller is pre-set by the laboratory to collect the sample over a five minute period. 1-Liter stainless steel canisters (e.g., SUMMA® canisters), hereafter "canisters", were used to collect samples at a rate of approximately 167mL/min, which is lower than the maximum sample collection rate identified in the IEPA TACO guidance (approximately 200 mL/min). Once the sample train was assembled, a vacuum leak check was performed.
- An enclosure was then placed over the VMP and the sample train assembled. The enclosure was sealed to the ground at each location with a hydrated bentonite seal.
- Helium gas was introduced into the enclosure until the atmosphere reached a concentration of approximately 50% helium.
- Three well volumes were purged from each VMP prior to sampling using a 15 milliliter (mL) hand pump. If the pump gauge held a vacuum or produced water when purged, the VMP screen was presumed to be occluded by groundwater or saturated and no sample was collected.
- After purging was completed, a soil gas sample was collected in a Tedlar® bag using a peristaltic pump. A Dielectric Technologies MGD-2002 (MGD-2002) field analyzer was then used to detect possible helium within the Tedlar® bag sample.
- Once the initial helium leak check was completed, the canister valve was opened to collect a sample for approximately five minutes or until a vacuum gauge reading of 5 inches Hg was observed. After sample completion, the canister valve was closed.
- A second Tedlar® bag was filled following the completion of the canister sampling. Soil gas readings were taken from the Tedlar® bag sample for total volatile organics with either a Thermo Scientific TVA 1000 Vapor Analyzer or a RAE® Systems ppbRae 3000 - PID and a Thermo Scientific TVA 1000 Vapor Analyzer - Flame Ionization Detector (FID); and for carbon dioxide (CO_2), methane (CH_4), lower explosive limit (LEL), and oxygen (O_2) with a Landtec GEM™ 2000 landfill gas meter. Readings were also obtained and recorded for helium with a MGD-2002 field analyzer. This check was used to verify the sample train integrity during and at the completion of sampling.
- At the completion of sampling, the canister and flow controller were removed and separated from the sample train and a final vacuum reading was recorded.
- Field duplicates were collected by including an additional T-connection in the sample train and attaching a second canister with a separate flow controller. Both the original and duplicate samples were started at the same time.

Field personnel and equipment underwent decontamination procedures to ensure the health and safety of those present, to maintain sample integrity, and to minimize cross-contamination. Non-disposable/reusable sampling equipment (e.g., compression fittings) was decontaminated prior to the collection of each analytical sample by spraying with Liquinox® and distilled water. For stainless steel vapor sampling equipment, a 15 mL hand pump was attached to the sampling apparatus and ambient air was pumped into the sampling apparatus to remove any internal dust particles or moisture. Personnel and small equipment decontamination was performed at the sample locations.

[11] The number of required VMPs in the sampling program varied over time with the installation of additional VMPs.

Eurofins Air Toxics, Inc. (Eurofins) of Folsom, California conducted the laboratory testing utilizing the following test methods:

- VOCs via Modified USEPA Total Organic-15 (TO-15) (including butane and isopentane) for soil gas, and
- Natural gases (defined for purposes of this Report as oxygen, nitrogen, carbon monoxide, methane, carbon dioxide, ethane, and ethene) via Modified ASTM D-1946 + Helium for soil gas.

Soil gas samples were analyzed for the following analytes via TO-15[12]:

Acetone	cis-1,3-Dichloropropene	Ethanol	Styrene
alpha-Chlorotoluene	Cumene	Ethyl Benzene	1,1,2,2-Tetrachloroethane
Benzene	Cyclohexane	4-Ethyltoluene	Tetrachloroethene
Bromodichloromethane	Dibromochloromethane	Freon 11	Tetrahydrofuran
4-Bromofluorobenzene	1,2-Dibromoethane (EDB)	Freon 113	Toluene
Bromoform	1,2-Dichlorobenzene	Freon 114	Toluene-d8
Bromomethane	1,3-Dichlorobenzene	Freon 12	1,2,4-Trichlorobenzene
1,3-Butadiene	1,4-Dichlorobenzene	Heptane	1,1,1-Trichloroethane
Butane	1,1-Dichloroethane	Hexachlorobutadiene	1,1,2-Trichloroethane
2-Butanone (MEK)	1,2-Dichloroethane-d4	Hexane	Trichloroethene
Carbon Disulfide	1,2-Dichloroethane	2-Hexanone	1,2,4-Trimethylbenzene
Carbon Tetrachloride	1,1-Dichloroethene	Isopentane	1,3,5-Trimethylbenzene
Chlorobenzene	cis-1,2-Dichloroethene	Methyl tert-butyl ether	2,2,4-Trimethylpentane
Chloroethane	trans-1,2-Dichloroethene	4-Methyl-2-pentanone	Vinyl Chloride
Chloroform	1,2-Dichloropropane	Methylene Chloride	m,p-Xylene
Chloromethane	trans-1,3-Dichloropropene	2-Propanol	o-Xylene
3-Chloropropene	1,4-Dioxane	Propylbenzene	

Volatile Organic Compound Sampling Results

A summary of the field-screened soil gas samples (i.e., Tedlar® bag samples) collected concurrently with the last eight quarters (3Q15 through 4Q16) of soil gas analytical samples is presented in **Table 3-2.** A historical table of results is provided in **Appendix 3-C**. A summary of field-screened soil gas samples collected during the last 24 months of Monthly Effectiveness Monitoring activities are presented in **Table 3-3.** Monthly Effectiveness Monitoring VMP sampling data is provided in **Appendix 3-D**. TO-15 results for the last eight quarters of soil gas samples collected in the Investigation Area are provided in **Table 3-4**, and a historical table of these results is provided in **Appendix 3-E.**

The vertical and horizontal distribution of hydrocarbons in soil gas prior to the SVE system (2011) and more recently after system startup (2012 to 2016) is depicted on **Figures 3-3** through **3-10**. **Figures 3-3** through **3-6** present the distribution of Total Hydrocarbon Concentration (THC) in soil gas over time in the Village at 5, 10, 20, and 30 feet bgs, respectively. **Figures 3-7** through **3-10** present the distribution of benzene concentration in soil gas over time in the Village at 5, 10, 20, and 30 feet bgs, respectively. These figures were generated using EVS to create a 3-dimensional model which depicts the distribution of THC throughout the Investigation Area. For presentation purposes in this Report, depth specific horizontal slices are presented (5, 10, 20, and 30 feet bgs) and represent interpolations and extrapolations of measured data. The bottom of the model represents an average potentiometric groundwater surface.

The data depicted in **Figures 3-3** through **3-10** indicate that prior to SVE installation elevated hydrocarbon concentrations were present in the SVE wells screened within vadose zone in the Investigation Area. The figures show that hydrocarbon and benzene concentration decreased significantly after the SVE system became operational. These reductions in concentration at shallow (approximately 0-10 feet bgs) to intermediate (approximately 10-20 feet bgs) depths have continued through 4Q16 and indicate that the SVE system has remediated significant portions of the Investigation Area. However, elevated hydrocarbon and benzene concentrations remain at deeper (greater than 20 feet bgs) VMPs within the Investigation Area. **Exhibit 3-1** and **Exhibit 3-2** below depict the reductions in benzene soil gas concentration over time at depths in the shallow and intermediate (10-20 feet bgs) zones.

[12] Naphthalene is not an analyte on the project's TO-15 analyte list; however, analytical results for naphthalene were requested in February 2017 for 1Q13 and 4Q16. Results are presented in **Table 3-4** and **Appendix 3-E.**

Exhibit 3-1: Benzene in Shallow Soil Gas Over Time (10 feet bgs) (Figure 3-8)

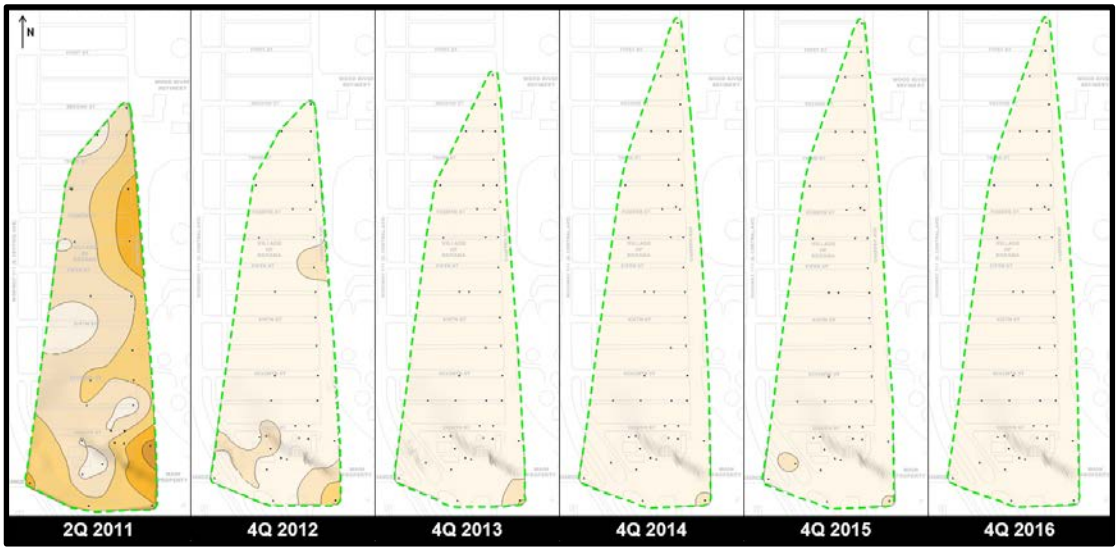


Exhibit 3-2: Benzene in Intermediate Soil Gas Over Time (20 feet bgs) (Figure 3-9)

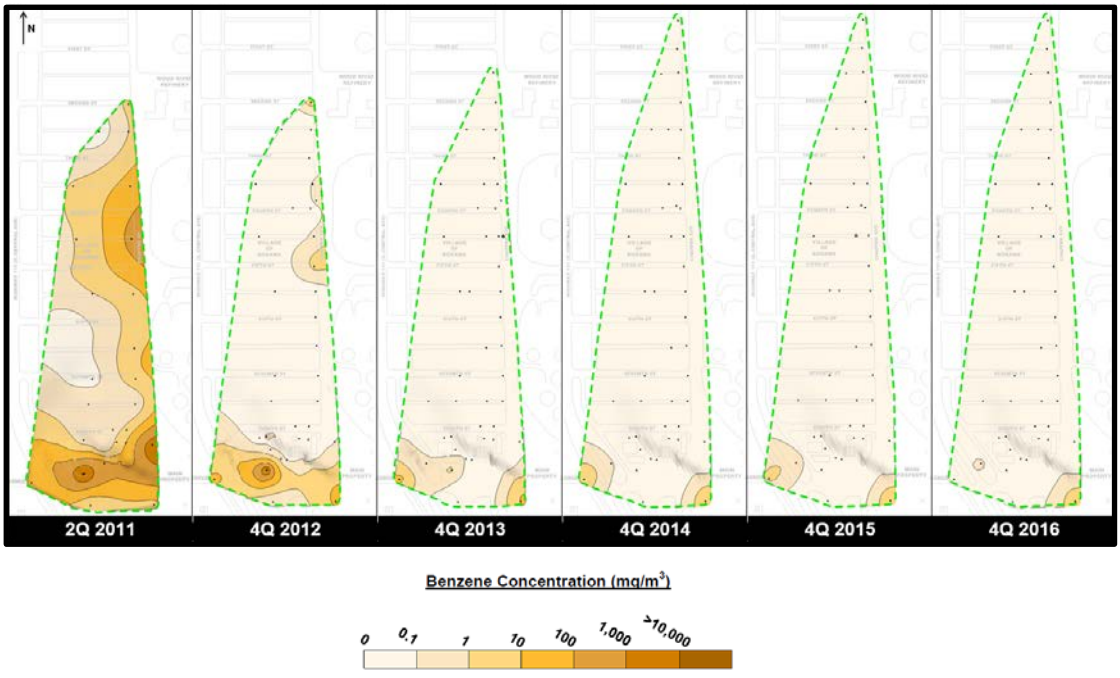

Methane and Natural (Fixed) Gases Sampling Results

A summary of the natural (fixed) gas results for the last six quarters is presented in **Table 3-5**, while a historical summary of these results can be viewed in **Appendix 3-F**. The vertical and horizontal distribution of pre-SVE system and post-SVE system methane in soil gas is depicted on **Figures 3-11** through **3-14**, showing the methane distribution in soil gas over time in the Village at 5, 10, 20, and 30 feet bgs, respectively. Similar to the results seen with hydrocarbons above, elevated methane levels were present in the shallow vadose zone before the SVE system became operational and quickly decreased after the system came on-line. **Exhibit 3-3** and **Exhibit 3-4** below depict the temporal change of methane in soil gas over time in the shallow (0-10 feet bgs) and intermediate zones (10-20 feet bgs).

Exhibit 3-3: Methane in Shallow Soil Gas Over Time (10 feet bgs) (Figure 3-12)

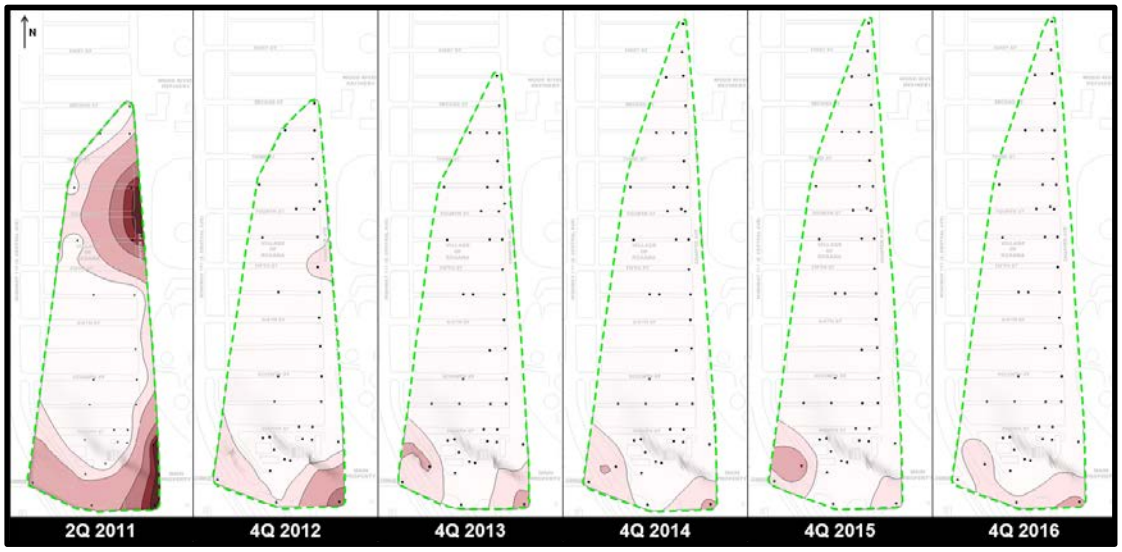

Exhibit 3-4: Methane in Intermediate Soil Gas Over Time (20 feet bgs) (Figure 3-13)

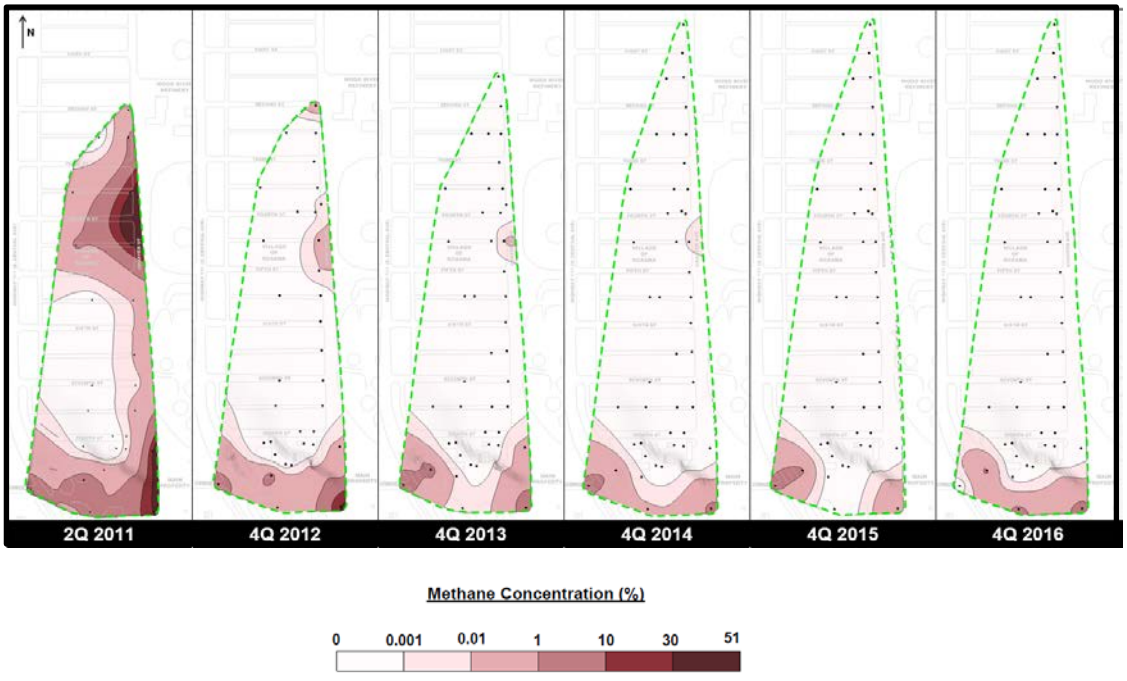


Natural (fixed) gas data indicate that, where petroleum impacts are present, the concentration of methane increases from shallow to deep sample depths, while oxygen concentrations decrease from shallow to deep sample depths (methane and oxygen are generally inversely correlated in soil gas). The trend in oxygen levels in most VMPs has been generally increasing, while methane levels have been generally decreasing since the SVE system has been operating. Oxygen levels appear to be increasing in VMPs closer to the SVE system (e.g., along Chaffer Avenue) in the Village and carbon dioxide levels are relatively high throughout the soil column at many locations. The combination of low oxygen, high carbon dioxide and elevated methane levels is indicative that degradation of petroleum hydrocarbons is occurring via aerobic biodegradation.

3.4 Indoor Air

Indoor Air and Sub-slab Soil Gas Sampling

Indoor residential sampling was conducted within the Investigation Area in accordance with the requirements established in a letter from the IEPA dated April 6, 2011 (IEPA, 2011b). Residential sampling was conducted from 2011 to 2013, with the majority of sampling taking place before the SVE system start up on January 31, 2012. The structures that were sampled are shown on **Figure 3-15**. An initial set of residences was identified, and notification letters were sent to those residences on February 3, 2011. Further, any additional residents within the Investigation Area were allowed to opt into the indoor sampling program. This program continues through 4Q16. Sampling proceeded at those residences whose property owners signed an access agreement. Fifty-five structures have been sampled as of December 31, 2016.

Prior to sampling, a walk-through assessment survey was conducted, and included a visual inspection of the residence and an interview with the building owner/occupant. The owner/occupants were asked to remove any potential indoor emission sources at least 48 hours prior to sampling. Additionally, the location of drains, cracks, and utility entrances were noted and a sketch of the basement layout (or first floor if basement was not present) was made. IEPA and/or IDPH were typically onsite during the initial meeting with the owner/occupant.

Prior to sample collection, indoor air was screened using FID, PID, and LEL meters and a methane detector. Measurements were collected from the first floor, basement (if present), and crawl space (if present). Measurements in basements were collected within two inches of drains, and at any wall or floor penetrations. IEPA and/or IDPH were typically onsite during indoor air sampling events.

Indoor Air and Sub-slab Soil Gas Sampling Overview

Indoor air samples were collected via 6-Liter stainless steel canisters, three to five feet above floor level, over a 24-hour period, and in accordance with relevant SOPs. If present, samples were collected in a basement, the central living area of the first floor, the entrance to a crawl space, and in an attached garage. At residences where indoor air samples were collected, a corresponding upwind, outdoor air sample was also collected. Indoor air samples were analyzed via Modified USEPA Method TO-15 (low level) and Modified ASTM D-1946 (methane only) and screened against residential indoor air criteria. Outdoor and attached garage samples were analyzed via Modified USEPA Method TO-15 (low level).

Indoor and outdoor air samples were analyzed for the following petroleum hydrocarbons:

Benzene	n-Propylbenzene
Toluene	Isopentane
Ethylbenzene	n-Butane
m,p-Xylene	Cyclohexane
o-Xylene	2,2,4-Trimethylpentane
1,2,4-Trimethylbenzene	1,4-Dioxane
1,3,5-Trimethylbenzene	TPH-g
n-Hexane	Methane

Sub-slab soil gas samples were collected via 1-Liter stainless steel canisters over a two-hour period at up to three locations per basement, in accordance with relevant SOPs. Sub-slab monitoring points (SSMPs) were installed by drilling a hole through the concrete slab in a location which minimized visible floor damage. A Tedlar® bag sample was collected from the SSMP and was screened with FID, PID, LEL meters and a methane detector. A sample shroud with helium tracer gas was used to detect any leaks in the sub-slab sampling process. Expandable concrete was used to repair damage to the concrete slab prior to leaving the residence. Sub-slab samples were analyzed via Modified USEPA Method TO-15 (standard) and modified ASTM D-1946 + helium.

Sub-slab soil gas samples were analyzed for the same petroleum hydrocarbons above plus helium, oxygen, nitrogen, carbon dioxide, carbon monoxide, ethane, and ethene.

Indoor Air and Sub-slab Soil Gas Sampling Results

Either an indoor air FID reading greater than 20 ppm or an indoor air LEL reading greater than zero was observed on two occasions at the time of sampling. However, the two occurrences of elevated FID or LEL readings in indoor air observed during the project were both attributable to natural gas leaks present within the respective residences. There were three occasions where a sub-slab FID reading greater than 500 ppm or a sub-slab LEL greater than zero was recorded. This occurred at the residences at [redacted]. As discussed in **Section 1.1**, the residents were offered alternative housing and mitigation measures at their respective properties during the interim measures period.

Data for indoor air were compared to project-specific screening levels as contained in the Vapor Intrusion Investigation Work Plan. These levels are summarized in **Exhibit 3-5** below.

Exhibit 3-5: Residential Indoor Air Screening Criteria

Constituent	Screening Level (mg/m^3)
Benzene	0.010 0.029 (acute)
Toluene	5.2
Ethylbenzene	a
m,p-Xylene	0.73
o-Xylene	0.73
1,2,4-Trimethylbenzene	0.0073
1,3,5-Trimethylbenzene	a
n-Hexane	0.73
n-Propylbenzene	1.0
Isopentane	a
n-Butane	a
Cyclohexane	6.3
2,2,4-Trimethylpentane	a
1,4-Dioxane	a
TPH-g	a
Methane	a

(a) – No screening level has been established for this constituent or category. Data were generated for informational purposes only.

A summary of indoor and outdoor air sampling results is presented in **Table 3-6**. Results of the indoor air sampling indicated the presence of most of the target constituents below the IEPA approved project screening levels at the majority of the properties sampled. In addition to the LEL and FID results, indoor air detections above the project screening levels in **Exhibit 3-2** were observed at seven residences during the project. IDPH reports that the contaminant concentrations detected in indoor air at non-smokers' homes and in public buildings were not at levels that would present a health concern for residents or occupants. At a few homes where tobacco smoking was an additional indoor source of benzene, concentrations of benzene were detected above IEPA approved project screening levels; however, in most of those cases, the benzene vapor concentrations beneath the home were low, and in each case IDPH determined the indoor air benzene concentrations were not attributable to petroleum product vapor intrusion (IEPA, 2013).

Data associated with sub-slab soil gas samples were compared to IEPA's Tier 1 soil gas remediation objectives, as presented in 35 IAC Part 742, Appendix B, Table H. These levels are summarized in **Exhibit 3-6** below.

Exhibit 3-6: Residential Sub-slab Soil Gas Screening Criteria

Constituent	Screening Level (mg/m^3)
Benzene	0.37
1,4-Dioxane	0.22
Ethylbenzene	1,400
Toluene	6,200
m,p-Xylene	130
o-Xylene	120

A summary of sub-slab sampling results is presented in **Table 3-7**. Results of the sub-slab sampling indicated detections of target constituents were below the project screening levels with a few exceptions. Exceedances of project screening levels were observed at [redacted]. The sub-slab exceedances were observed before the SVE system became operational along the West Fenceline. Resamples were collected from sub-slab monitoring points that exhibited an exceedance after SVE system startup (except for [redacted] where access as not given) and concentrations decreased to levels below the screening criteria.[13] This indicates that the sub-slab exceedances were remediated by the SVE system.

3.5 Conceptual Site Model

The CSM for soil and soil gas is structured on the current understanding of Site conditions based on information presented in **Section 3**. Two CSMs are presented in this Section. The first is from a time period prior to SVE system startup (Pre-SVE Conceptual Site Model), and the second represents current Site conditions (Present-Day Conceptual Site Model). The reason for this distinction is that the SVE system has substantially improved soil gas quality at the Site; as such, both scenarios are important to fully understand Site conditions.

3.5.1 Pre-SVE Conceptual Site Model

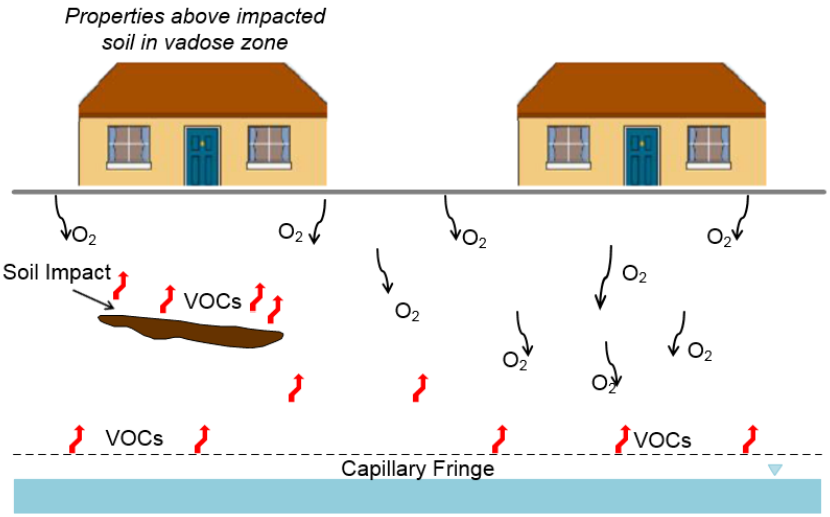
The CSM diagram for pre-SVE conditions is shown in **Exhibit 3-7** below. The data indicate that impacted soil and soil gas existed beneath limited areas in the eastern portion of the Site along Chaffer Avenue and limited areas in the southern portion of the Site in proximity of the Public Works Yard. Prior to operation of the SVE system, portions of the Site contained elevated concentrations of aromatic hydrocarbons (e.g., BTEX) in soil gas at the shallow and intermediate depths. The data indicate that the impacted shallow soil gas originated from hydrocarbon-impacted low permeability soils at intermediate depths in the vadose zone which were volatilizing and moving upward through the soil column. Elevated concentrations in soil and soil gas at depth (greater than 20 feet bgs) were a result of fluctuations in groundwater elevation within the dissolved phase plume[14]. Data suggests oxygen levels in the areas of the Site where intermediate soil impact was observed were lower than in areas without intermediate soil impact. This observation is likely the result of biodegradation activity occurring at a shallower depth than in areas with only deeper contamination.

Due to the nature of the constituents present at the Site, vapor intrusion into residences is the primary exposure pathway of concern at the Site. Although sub-slab soil gas samples from a limited number of residences contained elevated hydrocarbon concentrations, indoor air sampling did not identify vapor intrusion as discussed in **Section 3.4**.

[13] Soil gas samples were collected at [redacted] using Tedlar® bags through September 20, 2012 as a canister sample was unable to be collected. Measured FID concentrations were significantly lower than in the FID concentration measured concurrently with canister sample.

[14] On April 16, 2015, AECOM, on behalf of SOPUS, submitted a demonstration to verify the extent of groundwater contamination has been delineated (AECOM, 2015b). The demonstration is based on monitoring data from wells in the Roxana Interim Groundwater Monitoring Program. Additional information was submitted to IEPA in a letter dated January 29, 2016 (AECOM, 2016a). In a letter dated February 23, 2016 (IEPA, 2016), IEPA agreed with this determination and required a Groundwater Management Zone (GMZ) proposal be submitted within 90 days. The GMZ proposal was submitted by AECOM, on behalf of SOPUS on May 19, 2016 (AECOM, 2016c).

Exhibit 3-7: Pre-SVE CSM

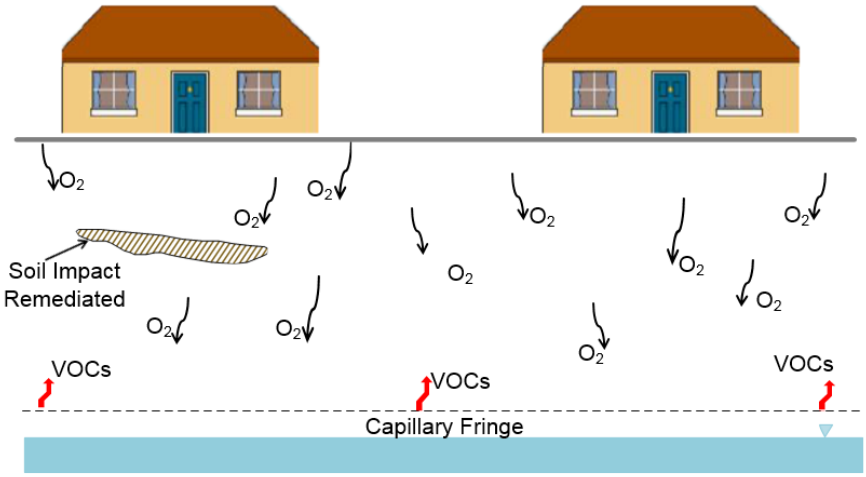


3.5.2 Present-Day Conceptual Site Model

The CSM diagram for present-day conditions is shown below (**Exhibit 3-8**). The present-day model accounts for the significant improvements observed from operation of the SVE system for the past five years and ongoing biodegradation. In the present-day model, the impacted soil gas in the shallow and intermediate depths of the vadose zone has been remediated, and the impacted soil in the intermediate depths of the vadose zone no longer appear to be a source of aromatic hydrocarbons.

With the remediation of shallow and intermediate impact through operation of the SVE system as well as biodegradation, oxygen levels observed in the shallow and intermediate zones have increased such that an aerobic environment is present deeper into the soil column, allowing for continued biodegradation of the impact in the deeper zones which are affected by fluctuations in groundwater elevation.

Exhibit 3-8: Present-Day CSM



4 SVE System Overview

As discussed in previous sections, operation of the RTO SVE system commenced on January 31, 2012. **Section 4** provides an overview of the SVE system, operation and maintenance activities, and the temporal and spatial trends in soil gas observed in response to its operation.

4.1 Description of SVE System

4.1.1 SVE System Design

The SVE system consists of 45 SVE wells, thirty of which are located along the West Fenceline, nine are located in the Village along 4th Street, west of Chaffer Avenue, and six are located in the Public Works Yard. The system was installed in three phases: (1) the initial system, (2) extension 1, and (3) extension 2. See **Figure 4-1** for the SVE system layout and **Figure 1-2** for VMP locations and installation dates.

Initial System: The initial SVE system installation consisted of thirty-four SVE wells (SVE wells 3 through 36). SVE wells 1 and 2 were installed as part of pilot testing but were not connected to the permanent system. All wells except SVE wells 21 through 24, 26, 27 were brought on-line on January 31, 2012 details associated with this were documented in the S*VE System Construction Completion Report*, dated May 30, 2012 (URS, 2012). Construction activities related to connection of SVE wells 21 through 24, 26, 27, located in the Public Works Yard, were completed in November 2012 and the wells were brought on-line on December 6, 2012. Details associated with the installation of Public Works Yard SVE wells were documented in the *SVE System Construction Completion Report, Addendum No.1*, dated February 14, 2013 (URS, 2013a).

Extension 1: During 3rd Quarter 2013 (3Q13), URS designed an extension to the northernmost extent of the West Fenceline portion of the SVE system. Five additional SVE wells (SVE wells 37 through 41) and six additional VMPs (VMPs 56 through 61) were installed in August 2013 for extension of the red header line, which was completed in October 2013. All newly installed SVE wells were open and on-line by November 2013. Details associated with this system extension were documented in the *SVE System Construction Completion Report, Addendum No.* 2, dated January 9, 2014 (URS, 2014a).

Extension 2: During 3rd Quarter 2014 (3Q14) and 4th Quarter 2014 (4Q14), AECOM designed and constructed an extension to the West Fenceline portion of the SVE system on Shell-owned properties adjacent to 4th Street and Chaffer Avenue. Six additional SVE wells (SVE wells 42 through 47) were installed for the blue line extension in August 2014 and were brought on-line in November 2014. Details associated with this system extension were documented in the SVE System Construction Completion Report, Addendum No. 3, dated March 4, 2015 (AECOM, 2015a).

The location of each SVE well was selected based on evaluation of soil, soil gas, CPT, and ROST™ data. SVE well screens were installed at shallow and deep intervals to target specific zones where petroleum impact was observed. The SVE well screens for the wells along the West Fenceline portion of the Site generally alternate between shallow and deep intervals. Pilot testing efforts suggested a potential ROI in excess of 90 feet; however, a conservative design ROI of 60 feet was used for each SVE well (URS, 2011b). A design ROI of 30 feet was used for SVE-45 because this well is screened over a smaller interval to target impacts within and below a silty sand (lower permeability) layer (AECOM, 2015a).

4.1.2 Soil Gas SVE Treatment System

The SVE wells are connected via 4-inch diameter piping to vapor/liquid separators (VLSs) and a rotary lobe positive displacement blower housed within a customized intermodal freight container (“conex”). Piping from the SVE wells feeds into one of six header lines, which lead to the conex, where vapor moves through the VLSs, before traveling through the blower and a baffle connected to a RTO. Each of the six header lines have been designated a color (i.e., - red, blue, green, teal, purple, and brown). A system fan located on the RTO side of the baffle pushes the vapor into the RTO and adds fresh air to dilute the vapor stream to control temperatures, as necessary. See **Figure 4-2** for the RTO system layout.

The RTO consists of two combustion chambers and burners with a tertiary and combustion air blower, temperature and pressure sensors, fuel control system, and main Programmable Logic Controller (PLC) based control panel. Recovered soil vapors are mixed with atmospheric (combustion) air provided by the combustion blower and natural gas (as needed) in the burner, and the mixture is then ignited. The inlet (cold face), outlet (stack), and combustion chamber temperatures are monitored and displayed on the Human Machine Interface (HMI). The amount of natural gas and/or ambient air added is automatically controlled to maintain operating temperatures. If the hydrocarbon concentrations in soil gas are sufficiently high and the combustion chamber temperature exceeds the established temperature set point, additional atmospheric air is automatically introduced into the combustion chamber by means of the tertiary blower and/or dilution air dampers near the "mixing box". Supplemental fuel and dilution air is controlled by a PLC-based control panel, and the control panel PLC is connected via Ethernet cable to the main computer in the control room through a router. Data collected by the PLC is logged on the computer and displayed on the HMI. Dilution air may also be introduced into the RTO by manual means, utilizing the manual dilution valve adjacent to the blower or the three supplementary dilution lines installed at the header.

Exhaust from the RTO is discharged to the atmosphere through a velocity duct exhaust stack which extends approximately 35 feet above ground surface. The stack temperature is monitored and displayed on the HMI. If stack temperatures exceed the established set point, a high stack temperature alarm will be triggered and the system will automatically shut down. Typical vapor destruction efficiencies are over 95-percent (AECOM, 2016b). **Exhibits 4-1** through **4-3** below contain photos of SVE system components.

Exhibit 4-1: Photo of SVE Treatment System (October 7, 2016)

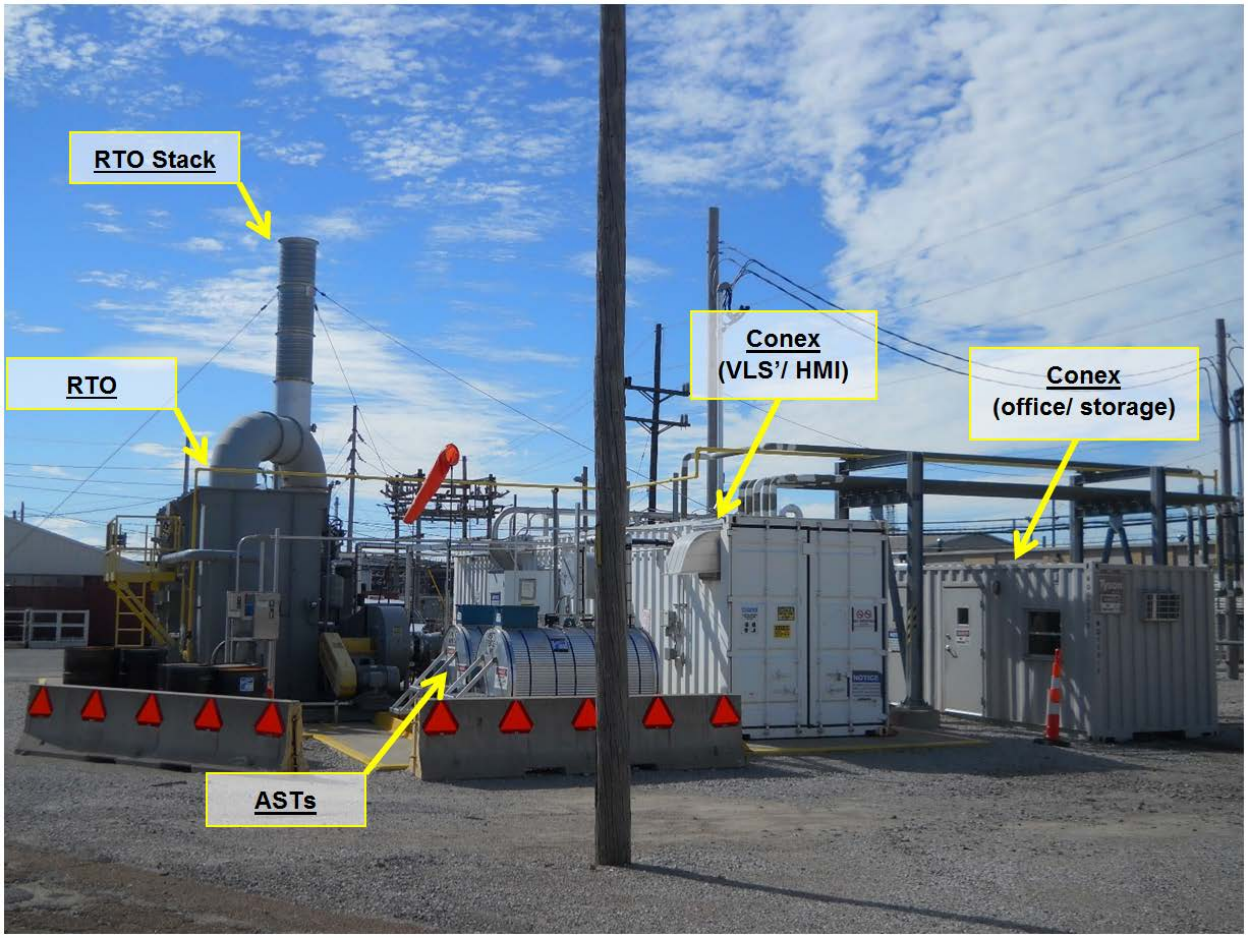


Exhibit 4-2: Photo of Header Lines (URS, 2012)

Exhibit 4-3: Photo of Typical West Fenceline SVE Well Vault (URS, 2012)

4.1.3 SVE System Operation

The SVE system is operated in accordance with the SVE Operation and Maintenance (O&M) Plan dated February 2016 (AECOM, 2016b). Since SVE system start up on January 31, 2012, the SVE wells and RTO have operated continuously, with short periods of down time due to scheduled maintenance or unscheduled events such as power outages. The IEPA is notified via email any time the SVE system is down for more than 72 continuous hours per the requirements of the April 9, 2014 letter from the IEPA (IEPA, 2014). The average annual runtime since SVE system start up is 93-percent[15].

The RTO system is effectively operated by directing vacuum to areas of greatest need by turning off SVE wells where soil gas concentrations have substantially diminished. As soil gas data collected from individual VMPs and SVE wells suggest the diminished concentrations of hydrocarbons within a particular area, an SVE well or wells are evaluated to be turned off. If the data supports shutting of an SVE well, surrounding VMPs are monitored bi-weekly for four weeks after the SVE well has been shut off[16]. This monitoring effort is in addition to the regularly scheduled monitoring events (monthly and quarterly). If no rebound is observed, the VMP will return to the regular monitoring schedule and the SVE well remains closed.

By closing SVE wells that have a low or insignificant hydrocarbon mass removal, energy is re-directed to other SVE wells and allows for more efficient operation of the RTO with less usage of supplemental fuel (natural gas). **Figure 4-3** shows active and inactive SVE wells including the closure date (if applicable). Additional information specific to well closure is presented in **Section 4.2.2**.

4.1.4 SVE System Maintenance

Regular maintenance activities (daily, weekly, monthly, and annual) are outlined in the SVE O&M Plan and are performed in accordance with manufacturer recommendations (AECOM, 2016b). A Performance Maintenance Evaluation (PME) is performed on an annual basis by the RTO manufacturer which is a thorough evaluation of the RTO's components. The manufacturer provides a report outlining findings and recommended maintenance or equipment repairs/replacements, which are implemented as deemed necessary.

4.1.5 Soil Gas Monitoring Programs

Monthly Effectiveness Monitoring

Monthly Effectiveness Monitoring is currently conducted in accordance with the requirements established by IEPA in a letter dated April 9, 2014 (IEPA, 2014)[17]. The soil gas sampling network currently consists of 63 VMP locations, of which 51 locations are currently utilized for monthly monitoring. VMPs in the sampling programs are generally screened at four depths[18] at each location. Operating SVE wells are also included in the monthly monitoring program. Soil gas samples are collected in Tedlar® bags from the VMPs and SVE wells and are screened for:

- Volatile organics f and methane with a Thermo Scientific TVA 1000 Vapor Analyzer or a RAE® Systems ppbRae 3000 - PID and a Thermo Scientific TVA 1000 Vapor Analyzer - FID and
- CO_2, CH_4, LEL, and O_2 with a Landtec GEM™ 2000 landfill gas meter.

Quarterly Soil Vapor Monitoring

The Quarterly Soil Vapor Monitoring program is also performed in accordance with IEPA's letter dated April 9, 2014. Of the existing 63 VMP locations, 46 are currently utilized for quarterly sampling. 1-Liter stainless steel canister samples are collected from each VMP location in the program and analyzed for the constituents listed in **Section 3.3**.

[15] Based on 24 hours per day, 365 days per year (8760 hours per year).

[16] Tedlar® bag samples are collected from relevant VMPs and analyzed for total volatile organics (THC, PHC) and methane as well as O_2, CO_2, and LEL.

[17] The Monthly Effectiveness Monitoring program has been consistently carried out since system inception; however, the program was not defined by IEPA until April 9, 2014.

[18] With the exception of single shallow ports at VMP-17, 18, and 19, three ports at VMP-41 through VMP-45 and VMP-56, and five ports at VMP-3.

The soil gas samples collected as part of the monthly monitoring program are collected simultaneously with the quarterly soil vapor monitoring samples and field screened. Results of the monthly and quarterly sampling events are presented in reports that are submitted to the IEPA on a quarterly basis.

4.1.6 System Monitoring and Permit Requirements

The SVE system operates under a Joint Construction and Operating Permit (Permit No. 119090AAO), issued by the IEPA on July 14, 2011. The Joint Construction and Operating Permit expired 18 months after the date of issuance; however, a timely application for a Federally Enforceable State Operating Permit (FESOP) was made. An application for a FESOP was submitted to the IEPA on April 11, 2012. The FESOP application is currently pending and as of the date of this Report, the system continues to operate in compliance under the 2011 Joint Construction and Operating Permit.

One of the requirements of the Joint Construction and Operation Permits is a limit on volatile organic material (VOM) and hazardous air pollutant (HAP) emissions. To monitor emissions, compliance canister samples are collected on a monthly basis from the system headers and RTO exhaust. The canisters are analyzed by EPA Method TO-15. Records are kept in accordance with the requirements of Permit No. 119090AAO. An Air Emissions Report (AER) is submitted to the IEPA on an annual basis, reporting system emissions for the reporting year.

Condition 11 of the September 13, 2012 letter from the IEPA which provided a response to several submittals made by SOPUS regarding investigation and remediation efforts to address contamination present along/near the West Fenceline, outlined monitoring requirements that are carried out on a monthly basis to monitor the general operational effectiveness of the system. These results and the results of the header and exhaust samples are reported on a quarterly basis in the Quarterly Soil Vapor and SVE Monitoring Reports. Prior to issuance of the September 13, 2012 letter, monitoring was being performed in accordance with project-specific monitoring procedures. Those procedures were consistent with the monitoring requirements established in Condition 11 of the aforementioned letter.

A performance test of the RTO was requested by IEPA in a letter dated April 12, 2013. The testing was conducted by Geosyntec Consultants on June 25 - 26, 2013. The RTO was demonstrated to effectively control hydrocarbons and benzene across the range of temperatures tested, achieving THC destruction efficiencies of 99.3%, 98.8%, and 98.8%, and benzene destruction efficiencies of >97.9%, >95.7%, and >96.3%. The results of the performance test were provided to the IEPA in a report dated August 21, 2013 (Geosyntec, 2013).

4.2 Temporal and Spatial Trends in Response to SVE System Operations

Since initial startup of the SVE system in 2012 and subsequent system extensions in 2013 and 2014, a significant reduction in hydrocarbon soil gas concentration has been observed in the VMP and SVE wells at the Site. The following discussion presents an overview of the temporal and spatial trends over time in response to SVE system operations.

4.2.1 Temporal and Spatial Soil Gas Trends

Figures 4-4 through **4-7** present the subsurface vacuum response to the SVE system over time at 5, 10, 20, and 30 foot depths from: (1) a time period after West Fenceline SVE system startup (January 31, 2012), (2) after Public Works SVE system startup (December 6, 2012), and (3) at approximately one year intervals through August 2016. The data presented in these figures are from monthly Effectiveness Monitoring events that coincided with the month that the Quarterly Soil Vapor Monitoring events were performed.

As shown on **Figures 4-4** through **4-7**, the system has generated effective vacuum response in strategic portions of the Site. Areas, such as 4th Street and Chaffer Avenue, demonstrate increasing vacuum over time throughout the entire soil column as a result of shutting off SVE wells and directing vacuum toward areas where THC concentrations remained.

Exhibit 4-4: Benzene Concentration Over Time (Figure 4-9)

As presented in **Section 3**, **Figures 3-3** through **3-14** show THC concentration (ppmv), benzene concentration (mg/m^3) and methane concentration (%) in soil gas over time at 5, 10, 20, and 30 foot depths. **Figures 4-8** through **4-10** compare THC, benzene, and methane concentrations in soil gas at 5, 10, 20, and 30 foot depths from a time period before interim system installation and start up in 2Q11, RTO System startup (January 31, 2012), and current (4Q16). These figures demonstrate the effectiveness of the SVE system from a time period before SVE system installation and 4Q16; the improvement in soil gas conditions is apparent.

Prior to SVE system installation, elevated soil gas concentrations were observed in the shallow to intermediate subsurface (0-20 feet bgs) in parts of the Site, particularly along portions of Chaffer Avenue between 5th and 7th Streets as well as in the proximity of 4th Street and Chaffer Avenue. These elevated concentrations were attributed to impact present in discontinuous lower permeability lenses of clay and silt, which acted as perching units for hydrocarbons. The discontinuous lower permeability lenses of clay and silts are depicted in the geological cross sections presented in **Figure 2-2**, **Figure 2-3**, and **Figure 2-4**.

As a direct result of operation of the SVE system, the source has been remediated from the perching units and resulting soil gas concentrations have been reduced to below TACO Tier 1 criteria for the shallow and intermediate VMP locations.

Exhibit 4-4 demonstrates the significant improvement in soil gas by the reduction in benzene concentration from a time period prior to system installation and 4Q16.

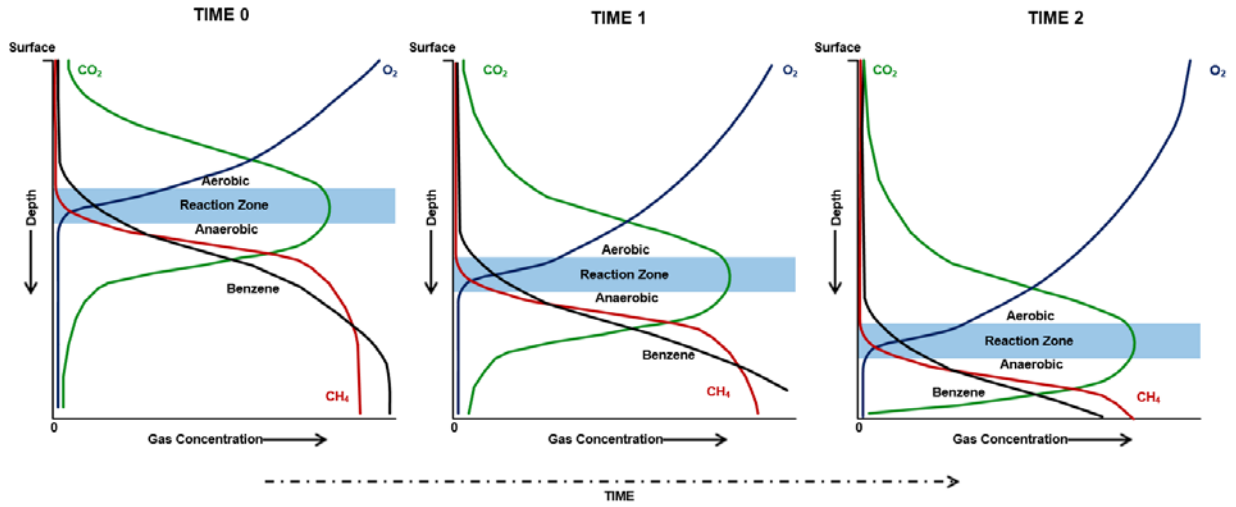
4.2.1.1 Soil Gas Composition Profiles

In addition to data collected to monitor the concentration of petroleum hydrocarbons over time, data collected regarding the overall composition of soil gas throughout the soil column provides a good indicator of the prevalence of degradation activity which may be occurring in the subsurface concurrent with the removal of hydrocarbon vapors by the SVE system. According to Interstate Technology Regulatory Council (ITRC), "*PHC-degrading bacteria are found in all environments and can consume hydrocarbons rapidly in the presence of O_2. This activity can limit transport and VI effects of PHC vapors*" (ITRC, 2014a).

Prior to startup of the SVE system, data collected from VMPs within the Investigation Area suggested the presence of an aerobic environment in the shallow subsurface, transitioning to an anaerobic environment deeper into the soil column. Higher oxygen levels (>5%) with lower methane levels indicate an environment capable of supporting aerobic biodegradation (Ririe et al., 1998). The transition from an aerobic to anaerobic environment coupled with an increase in soil gas concentration that is inversely related to the change in oxygen concentration suggests degradative activity. At some depth between the aerobic and anaerobic zones, there is a "reaction zone" where the transition from an aerobic to anaerobic environment occurs; this closely corresponds to the depth of the PHC constituents (ITRC, 2014d). Over time, as degradation and operation of the SVE system breaks down or removes the hydrocarbons, oxygen is more readily available and the aerobic zone extends deeper into the subsurface.

Exhibit 4-5 is an idealized example of the soil gas composition of benzene, methane, oxygen, and carbon dioxide over time that is observed in the presence of biodegradation. The zone above an area contaminated by a petroleum release is typically an aerobic environment in which oxygen can be readily replenished from the atmosphere (ITRC, 2014b).

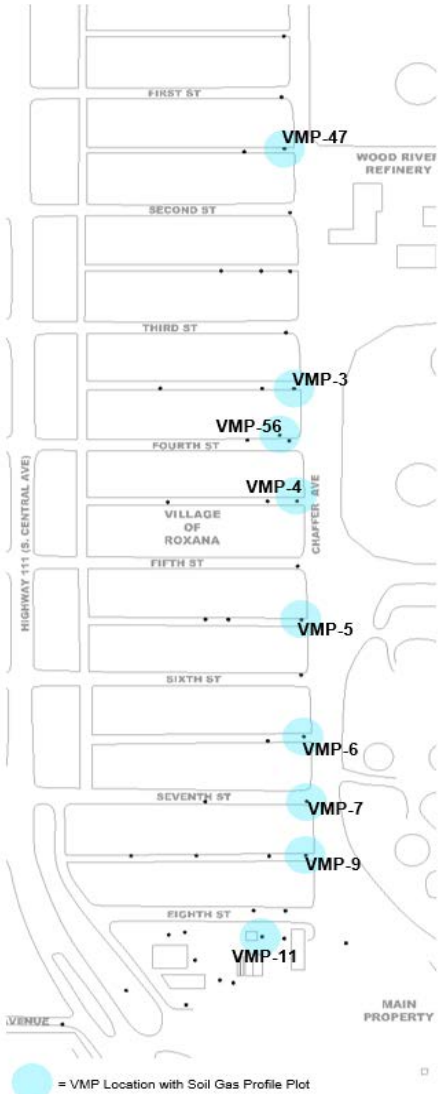
Exhibit 4-5: Idealized Soil Gas Profiles Over Time (ITRC, 2014c)



According to ITRC:

> *At some sites, it is desired to document the depth of the reaction zone where conditions change from aerobic to anaerobic in order to determine the thickness of the aerobic vadose zone separating the contamination source from the building. This determination can be made by conducting a vertical profile of soil gas concentrations using field tools to screen for the presence of VOCs, O_2, CH_4, and CO_2, which are indicator compounds of aerobic and anaerobic conditions (*see **Exhibit 4-5**). *In general, the depth of the anaerobic vadose zone closely corresponds to the depth of contaminated soil. PHC concentrations are relatively low in the aerobic zone (where O_2 is present), but can be quite high in the underlying anaerobic (O_2-absent) zone* (ITRC, 2014d).

Exhibit 4-6: Soil Gas Profile Plot Locations



Figures 4-11 through **4-19** contain soil gas profile plots over time for various VMPs throughout the Investigation Area. The locations of the VMPs associated with the soil gas profile plots are shown in **Exhibit 4-6**. Plots are shown from a period prior to SVE system installation, or a period shortly after VMP installation, and three time periods after. The data sets were chosen based on availability of data for all port depths, where possible. Based on the ITRC guidance, these figures further demonstrate the presence of biodegradation at the Site, with the aerobic zone extending deeper into the soil column and the anaerobic zone shrinking over time as soil gas is remediated and biodegraded. Certain VMPs are located within the ROI of SVE wells that have been closed since 2013. These locations are discussed further in **Section 4.2.2**.

Figure 4-20 shows north to south cross sections along Chaffer Avenue for benzene, methane, oxygen, and carbon dioxide. Similarly, **Figure 4-21** shows west to east cross sections along 4th Street for benzene, methane, oxygen, and carbon dioxide. These figures were generated using CTech™ EVS software. Both **Figure 4-20** and **4-21** show soil gas profile cross sections over time for a period before system installation (2Q11), after SVE system startup (January 31, 2012)) and the most current data set as of the date of this Report (4Q16). Conceptually, these figures demonstrate the same concept shown in plot format in **Figure 4-11** through **Figure 4-19**. The concentrations of benzene and methane have reduced considerably over time. Additionally, consistent with **Exhibit 4-5**, the temporal changes in distribution of benzene, methane, oxygen, and carbon dioxide in the subsurface overtime suggest the occurrence of aerobic biodegradation in the subsurface at the Site.

4.2.2 SVE Well Closures and Rebound Monitoring

As of December 31, 2016, 29 of 45 SVE wells are closed. A table containing SVE well status and the date on which it was closed, if applicable, is provided in **Exhibit 4-7** below and on **Figure 4-3**:

Exhibit 4-7: SVE Well Closure Status

Line	SVE Well	Screen Interval (ft. bgs)	Open/Closed (O/C) Date Closed	Line	SVE Well	Screen Interval (ft. bgs)	Open/Closed (O/C) Date Closed
Green	SVE-13	10-20	C - 2/20/15	Blue	SVE-3R	31-41	O

†*SVE-16 through 19 were opened on December 12, 2016 to provide additional supplemental dilution air to the RTO. The data presented in this section demonstrates VMP data collected prior to opening the aforementioned SVE wells.*

As mentioned in **Section 4.1.5**, VMPs surrounding SVE wells that have been closed are monitored for rebound bi-weekly for four weeks following well closure. No rebound has been observed in a VMP after a well has been closed. Although the SVE system is still in operation, areas of the Village where several wells have been turned off for more than a year suggest that rebound will not occur. For example, a stretch of eight SVE wells between 5th and 8th Streets are closed. These wells include:

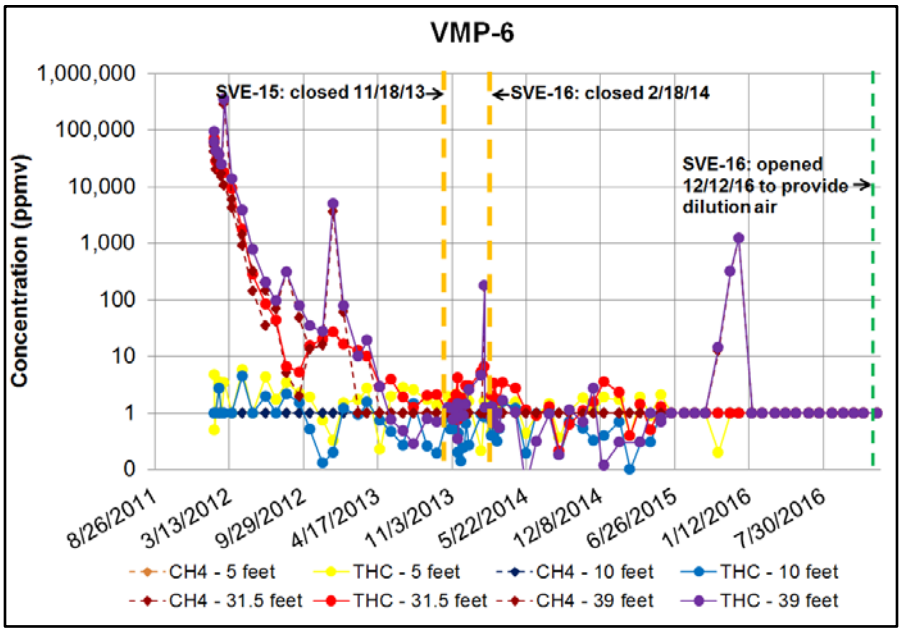
- SVE-15, SVE-17 and SVE-18 (closed in 2013)
- SVE-19 and SVE-35 (closed in 2014)
- SVE-13, SVE-14 and SVE-16 (closed in 2015)

VMPs within the Village that are nearest to these SVE wells include VMP-5, VMP-6, VMP-7, and VMP-45. Charts plotting THC and methane concentrations overtime for the aforementioned VMPs relative to closure dates of adjacent SVE wells are shown in **Exhibit 4-8**. Benzene and Methane trend plots for all VMPs included in the program are provided in **Appendix 4-A**. Based on the data collected at these VMPs, no rebound has been observed at these or other locations surrounding SVE wells after they were closed.

Exhibit 4-8: THC and Methane Trend Plots for Select VMPs adjacent to SVE wells between 5th and 8th Street

Notes: (1) Data is plotted using a logari hmic scale. Zero values were graphed as log(1).
(2) Vertical lines representing well closure dates are estimated.

VMP-6 is nearest to SVE-15 and SVE-16, which have been closed since November 18, 2013, and February 18, 2014, respectively. VMP-6 is monitored as part of the Monthly Effectiveness Monitoring program. THC and methane concentrations for each port depth (5, 10, 31.5, and 39 feet bgs) are shown on the plot to the right. Consistently low concentrations are observed, with the exception of elevated methane readings and resulting THC concentrations in December 2015 at the 39 foot port. Elevated hydrocarbon and methane levels at deeper VMPs are interpreted as being the result of fluctuations in groundwater elevation and are not considered to represent rebound of soil gas in the intermediate to shallow zones.



VMP-7 is nearest to SVE-18 and SVE-17, which have been closed since October 15, 2013, and October 17, 2013, respectively. VMP-7 is monitored as part of the Monthly SVE Effectiveness program. THC and methane concentrations for each port depth (5, 13.5, 29.5, and 38 feet bgs.) are shown on the plot to the right. A consistently low trend is observed at this VMP since late-2013 forward. Minor increases in THC and methane are observed in ealy-2015 and mid-2016 in the 38 foot port. Elevated hydrocarbon and methane levels at deep VMPs are interpreted as being the result of fluctuations in groundwater elevation and are not considered to represent rebound of soil gas in the intermediate to shallow zones.

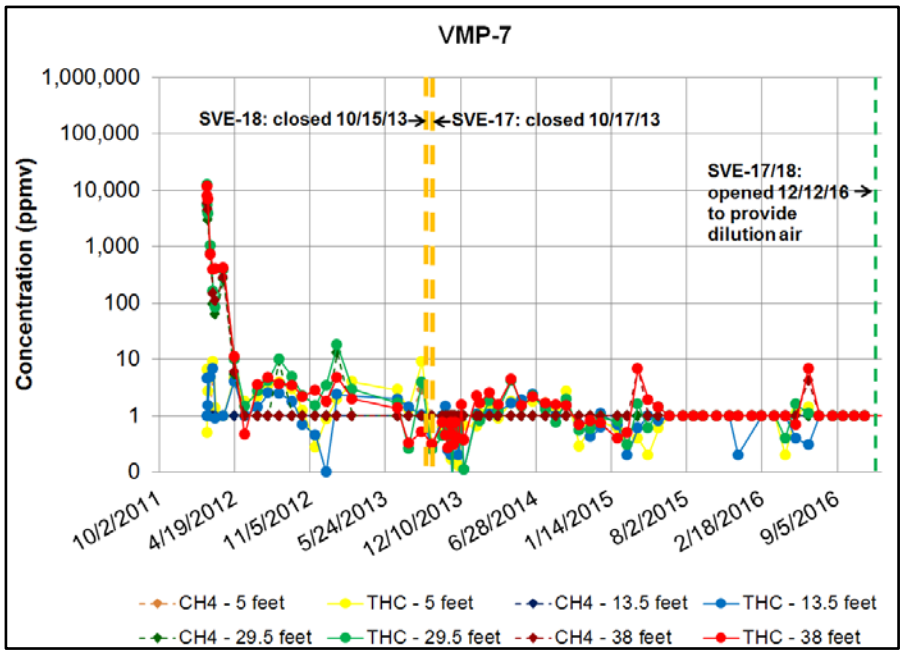


Exhibit 4-8 (continued)

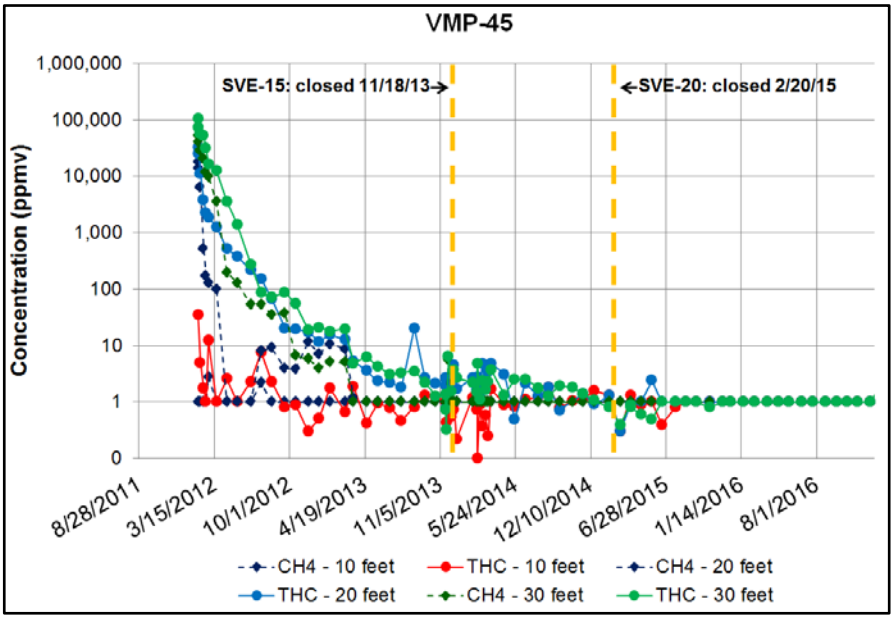
VMP-45 is nearest to SVE-15 and SVE-14, which have been closed since November 18, 2013, and February 20, 2015, respectively. VMP-45 is monitored as part of the Monthly Effectiveness Monitoring program. THC and methane concentrations for each port depth (10, 20, and 30 feet bgs.) are shown on the plot to the right. A consistently low trend is observed at this VMP since late-2013.



5 Conclusions

SOPUS has been conducting investigations and performing active remediation at the Site under the oversight of IEPA and IDPH for approximately 10 years. Both Agencies have provided technical input and approvals on an ongoing basis and, in coordination with SOPUS, have kept the community informed throughout the various investigations and remedial activities. The data collected through investigations and monitoring events have created an extensive database that has been used to characterize the Site and document the improvements that have occurred over time.

The following bullets summarize key points and conclusions that have been presented in Part 1 of this Report:

- Soil gas data collected over the past five years of SVE system operation demonstrate a significant reduction in hydrocarbon concentration in the subsurface, particularly in the shallow and intermediate zones.
- Site soil conditions have been assessed at over 190 soil boring locations. The information derived from the borings has demonstrated subsurface materials are primarily sands, along with the presence of relatively thin, discontinuous layers of finer-grained, lower permeability soils (silts and clays) located sporadically throughout the Site, typically at depths between approximately 20 to 30 feet bgs. Petroleum impacts were more apparent in the finer-grained materials.
- Over 330 soil samples have been collected for laboratory testing for compounds characteristic of petroleum hydrocarbons. These compounds were more pronounced in the discontinuous lower permeability soil zones prior to remediation and at depth (influenced by groundwater conditions).
- Over 3,300 soil gas samples have been collected and analyzed, and over 17,000 soil gas samples have been collected and field-screened. Collectively, the nature and extent of petroleum impacts in soil gas and the temporal changes that have occurred since startup of the SVE system are well defined.
- Indoor air and sub-slab conditions were evaluated at over 50 structures, with no instances of vapor intrusion. Most of the indoor air and sub-slab sampling occurred prior to construction of the SVE system. Petroleum vapors were elevated in soil gas beneath five homes, and even though indoor air was not affected, a conservative approach was adopted and interim measures were taken to mitigate sub-slab vapors until the SVE system was operational.
- Groundwater is being managed through the current groundwater monitoring program including the groundwater containment and treatment system. A GMZ proposal was submitted to the IEPA on May 19, 2016, and is pending as of the date of this Report. The GMZ was prepared as requested by the IEPA in their letter to SOPUS dated February 23, 2016 in which the IEPA agreed with the conclusion that groundwater within the Village of Roxana has been delineated (IEPA, 2016).
- The SVE system, installed in 2011 and subsequently extended in 2013 and 2014, consists of 45 SVE wells, over 50% of which have been closed over the past 3 years as soil gas data demonstrates the shallow and intermediate zones have been remediated. Soil gas concentrations at depth have also decreased over time but remain in certain areas partly due to fluctuating groundwater conditions.

In Part 2 of this Tier 3 Demonstration, the fate and transport of benzene and other VOCs are evaluated using mathematical models. The primary purpose is to determine soil gas concentrations at various depths that would be protective of human health. The calculated soil-gas concentrations are proposed Tier 3 remediation objectives and represent a concentration that would not lead to an exceedance of risk-based indoor air concentrations under conservative conditions for vapor intrusion or an exceedance of construction worker trench air screening levels (i.e., Rand Avenue and Route 111 Rights-of-Way). Using the proposed remediation objectives, Part 2 outlines a suggested system shutdown and a rebound monitoring program.

6 Statement of Limitations

SOPUS shall have the right to make and retain copies of and use all Work Product provided. However, such use shall be limited to the particular Site and project for which the Work Product is provided. SOPUS and its agents may release the Work Product to third parties at its sole risk and discretion. This document is based on data, site conditions, and other information that is generally applicable as of the date of this document, and the conclusions and recommendations herein are therefore applicable only to that time frame and to the document in its entirety. Certain information and other data used in preparing this document was furnished to AECOM by third parties. Information obtained from these sources is assumed to be correct and complete. AECOM will not assume any liability for errors or omissions of the third party supplied information.

AECOM has performed services described herein in a manner consistent with that level of care and skill ordinarily exercised by members of the same profession currently practicing in the same locality under similar conditions. DRN. BY: cem Feb. 2017 DSGN. BY: cem CHKD. BY: atd	Methane Concentration in Soil Gas Pre-SVE and 4th Quarter 2016 (5, 10, 20, 30 feet bgs)	FIG. NO. 4-10

Soil Gas Profile Plots Over Time
VMP-3

Pre-SVE ----------> **After SVE Startup** ----------

November 2009	July 2013	October 2014	February 2016
			• Intermediate and deep sources of impact • Elevated benzene and methane concentrations • Low oxygen, high carbon dioxide	• Intermediate zone remediated • Benzene and methane concentrations reduced • Oxygen replenished • Reaction zone deepening	• Reaction zone continues to deepen • Oxygen increasing at depth	• Deeper zone remediated • Oxygen replenished; conditions favorable for aerobic biodegradation

NOTES:

1.) INITIAL SYSTEM STARTUP OF WEST FENCELINE PORTION OF THE SOIL VAPOR EXTRACTION (SVE) SYSTEM WAS JANUARY 31, 2012. THE PUBLIC WORKS PORTION OF THE SVE SYSTEM WAS STARTED ON DECEMBER 6, 2012.

2.) DATA PRESENTED WERE COLLECTED DURING QUARTERLY SOIL VAPOR MONITORING EVENTS. DATES PRESENTED WERE CHOSEN BASED ON THE AVAILABILITY OF DATA AND ARE REPRESENTATIVE OF THE CHANGE IN SOIL GAS COMPOSITION OVER TIME.

3.) THE ZONE ABOVE AN AREA CONTAMINATED BY A PETROLEUM RELEASE IS TYPICALLY AN AEROBIC ENVIRONMENT IN WHICH OXYGEN CAN BE READILY REPLENISHED FROM THE ATMOSPHERE (ITRC, 2014A). MEASURED TEMPORAL CHANGES IN SOIL GAS COMPOSITION SUGGEST BIODEGRADATION REACTION ZONE GETS DEEPER OVER TIME AS THE SVE SYSTEM REMOVES SOURCE CONTAMINATION.

= Approximate representation of reaction zone

Cmax = Maximum benzene concentration at VMP (mg/m^3)

Soil Gas Profile Plots Over Time
VMP-4

Pre-SVE ----------> **After SVE Startup** ----------

November 2009	July 2012	August 2014	October 2016
			• Intermediate and deep sources of impact • Elevated benzene and methane concentrations • Low oxygen, high carbon dioxide	• Intermediate and deep sources of impact reduced • Benzene and methane concentrations reduced • Oxygen increasing at depth • Reaction zone deepening	• Intermediate and deep sources of impact reduced • Benzene and methane concentrations reduced • Oxygen replenished; conditions favorable for aerobic degradation	• Intermediate zone remediated • Benzene and methane concentrations reduced • Conditions favorable for aerobic biodegradation

NOTES:

1.) INITIAL SYSTEM STARTUP OF WEST FENCELINE PORTION OF THE SOIL VAPOR EXTRACTION (SVE) SYSTEM WAS JANUARY 31, 2012. THE PUBLIC WORKS PORTION OF THE SVE SYSTEM WAS STARTED ON DECEMBER 6, 2012.

2.) DATA PRESENTED WERE COLLECTED DURING QUARTERLY SOIL VAPOR MONITORING EVENTS. DATES PRESENTED WERE CHOSEN BASED ON THE AVAILABILITY OF DATA AND ARE REPRESENTATIVE OF THE CHANGE IN SOIL GAS COMPOSITION OVER TIME.

3.) THE ZONE ABOVE AN AREA CONTAMINATED BY A PETROLEUM RELEASE IS TYPICALLY AN AEROBIC ENVIRONMENT IN WHICH OXYGEN CAN BE READILY REPLENISHED FROM THE ATMOSPHERE (ITRC, 2014A). MEASURED TEMPORAL CHANGES IN SOIL GAS COMPOSITION SUGGEST BIODEGRADATION REACTION ZONE GETS DEEPER OVER TIME AS THE SVE SYSTEM REMOVES SOURCE CONTAMINATION.

= Approximate representation of reaction zone

Cmax = Maximum benzene concentration at VMP (mg/m^3)

Notes:

1. OVR is used to indicate a reading over range for the FID or MultiRAE.
2. The Landtec landfill gas analyzer displays "OVR" for any results calculated higher than 99.9% for an individual reading.
3. N/A is used to indicate that a reading was not collected because it was unnecessary (i.e., a direct port for helium if the helium leak check was successful). NM is used to indicate that a reading was not measured.
4. NS is used to indicate that a reading was not collected because the port could not be sampled.
5. FID readings were taken with a TVA-1000. Due to oxygen concentrations less than 16% a dilution tip was used when analyzing samples. The dilution tip introduced ambient air in a 10:1 ration with the sample, which required the sample readings to be multiplied by 10 to get the actual reading. The FID readings in this spreadsheet illustrate the actual FID values that were represented in each sample.
6. Negative readings on the FID are recorded as zero.
7. VMP successfully resampled after helium leak check failure.
8. VMP unsuccessfully sampled after three attempts due to helium leak check failures.
9. VMP resampled due to issues with the canister after arriving at the laboratory.
10. VMP not sampled due to pending re-installation.
11. VMP not sampled because screen submerged below water table.
12. VMP resampled to verify results from the laboratory.
13. VMP resampled due to elevated helium readings (>10% of shroud) in canister at the laboratory.
